## Chapter 1

## Introduction

### 1.1 Asymptotic Review

Recall from CS 240, that given a problem with instances $I$ of size $n$ :

Lecture 1
(05/09)

## Definition 1.1.1 (runtime)

The runtime of an instance $I$ is $T(I)$.
The worst-case runtime is $T(n)=\max _{\{I:|I|=n\}} T(I)$.
The average runtime is $T_{\text {avg }}(n)=\frac{\sum_{\{I: I \mid=n\}} T(I)}{|\{I:|I|=n\}|}$

Recall also the asymptotic comparison of functions $f(n)$ and $g(n)$ with values in $\mathbb{R}_{>0}$ :
Definition 1.1.2 (big- $O$ )
$f(n) \in O(g(n))$ if there exists $C>0$ and $n_{0}$ such that $n \geq n_{0} \Longrightarrow f(n) \leq C g(n)$.

Definition 1.1.3 (big- $\Omega$ )
$f(n) \in \Omega(g(n))$ if there exists $C>0$ and $n_{0}$ such that $n \geq n_{0} \Longrightarrow f(n) \geq C g(n)$. Equivalently, $g(n) \in O(f(n))$.

Definition 1.1.4 (big- $\Theta$ )
$f(n) \in \Theta(g(n))$ if there exists $C, C^{\prime}>0$ and $n_{0}$ with $n \geq n_{0} \Longrightarrow C g(n) \leq f(n) \leq C^{\prime} g(n)$. Equivalently, $f(n) \in O(g(n)) \cap \Omega(g(n))$.
Recall also that if $\lim _{n \rightarrow \infty} \frac{f(n)}{g(n)}$ is finite, then $f(n) \in \Theta(g(n))$.

Definition 1.1.5 (little-o)
$f(n) \in o(g(n))$ if for all $C>0$, there exists $n_{0}$ such that $n \geq n_{0} \Longrightarrow f(n) \leq C g(n)$.
Equivalently, $\lim _{n \rightarrow \infty} \frac{f(n)}{g(n)}=0$.

## Definition 1.1.6 (little- $\omega$ )

$f(n) \in \omega(g(n))$ if for all $C>0$, there exists $n_{0}$ such that $n \geq n_{0} \Longrightarrow f(n)>C g(n)$.
Equivalently, $\lim _{n \rightarrow \infty} \frac{f(n)}{g(n)}=\infty$ or $g(n) \in o(f(n))$.

Also, recall that any polynomial of degree $k$ is in $\Theta\left(n^{k}\right) .{ }^{1}$
We write $n^{O(1)}$ to mean at most polynomial (i.e., $O\left(n^{k}(n)\right)$ where $\left.k \in O(1)\right)$
Exercise 1.1.7. Is $2^{n-1}$ in $\Theta\left(2^{n}\right)$ ?

Proof. Notice that $2^{n-1}=\frac{1}{2} 2^{n}$. If we let $C=\frac{1}{2}=C^{\prime}, n_{0}=1$, notice that for $n \geq n_{0}$, we have $C 2^{n}=2^{n-1} \leq 2^{n-1} \leq 2^{n-1}=C^{\prime} 2^{n}$. That is, $2^{n-1} \in \Theta\left(2^{n}\right)$.

Exercise 1.1.8. Is $(n-1)$ ! in $\Theta(n!)$ ?
Solution. No. Notice that $\lim _{n \rightarrow \infty} \frac{(n-1)!}{n!}=\lim _{n \rightarrow \infty} \frac{1}{n}=0$. Therefore, $(n-1)!\in o(n!)$, which contradicts $(n-1)!\in \Theta(n!)$.

Consider now multivariate functions $f(n, m)$ and $g(n, m)$ with values in $\mathbb{R}_{>0}$. Then,

Definition 1.1.9 (multivariate big- $O$ )
$f(n, m)$ is in $O(g(n, m))$ if there exist $C, n_{0}, m_{0}$ such that $f(n, m) \leq C g(n, m)$ for $n \geq n_{0}$ or $m \geq m_{0}$.

We similarly define the other asymptotic analysis functions. We could alternatively define using $n \geq n_{0}$ and $m \geq m_{0}$ but they both give the same results.
Notice that all basic operations are not equal. For example, multiplication may take $O(b)$ time for a $b$-bit word.

Lecture 2
(05/11)

Warning: big- $O$ is only an upper bound, so $1 \in O\left(n^{2}\right)$ and $n \in O(n)$, but we know that $1 \ll n$.
Asymptotic notation hides constants. Any $\Theta\left(n^{2}\right)$ algorithm will beat a $\Theta\left(n^{3}\right)$ algorithm eventually. A galactic algorithm is practically irrelevant because the crossing point is stupidly large.

[^0]
### 1.2 Types of Algorithms

Problem 1.2.1 (contiguous subarrays)
Given an array $A[1 . . n]$, find a contiguous subarray $A[i . . j]$ that maximizes the sum $A[i]+\cdots+A[j]$.

Consider the brute-force attempt

```
Algorithm 1.2.2 BruteForce \((A)\)
    opt \(\leftarrow 0\)
    for \(i \leftarrow 1, \ldots, n\) do
        for \(j \leftarrow i, \ldots, n\) do
            sum \(\leftarrow 0\)
            for \(k \leftarrow i, \ldots, j\) do
                sum \(\leftarrow\) sum \(+A[k]\)
            if sum >opt then
                opt \(\leftarrow\) sum
    return opt
```

which has a runtime $\Theta\left(n^{3}\right)$. This is inefficient. We are recomputing the same sum in the $j$ loop, so if we instead keep the running sum:

```
Algorithm 1.2.3 BetterBruteForce ( \(A\) )
    opt \(\leftarrow 0\)
    for \(i \leftarrow 1, \ldots, n\) do
        sum \(\leftarrow 0\)
        for \(j \leftarrow i, \ldots, n\) do
            sum \(\leftarrow\) sum \(+A[j]\)
            if sum >opt then
                opt \(\leftarrow\) sum
    return opt
```

we get $\Theta\left(n^{2}\right)$.
We can develop a divide-and-conquer algorithm by noticing that the optimal subarray (if not empty) is either (1) completely in $A[1 . . n / 2]$, (2) completely in $A[n / 2+1 . . n]$, or (3) contains $A[n / 2]$ and $A[n / 2+1]$.

Each of MaximizeUpperHalf and MaximizeLowerHalf have runtime $\Theta(n)$, so DivideAndConquer has runtime $2 T(n / 2)+\Theta(n) \in \Theta(n \log n)$.

Finally, notice that we can instead solve the problem in nested subarrays $A[1 . . j]$ of sizes $1, \ldots, n$. The optimal subarray is either a subarray of $A[1 . . n-1]$ or contains $A[n]$.

Write $M(j)$ for the maximum sum for subarrays of $A[1 . . j]$. Then,

$$
M(n)=\max (M(n-1), \bar{M}(n))=A[n]+\max (\bar{M}(n-1), 0)
$$

```
Algorithm 1.2.4 DivideAndConquer \((A)\)
    if \(n=1\) then return \(\max (A[1], 0)\)
    \(o p t_{l o} \leftarrow \operatorname{DivideAndConQUER}(A[1 . . n / 2])\)
    \(o p t_{h i} \leftarrow \operatorname{DivideAndConQUER}(A[n / 2+1 . . n])\)
    function MaximizeLowerHalf()
        opt \(\leftarrow A[n / 2]\)
        sum \(\leftarrow A[n / 2]\)
        for \(i \leftarrow n / 2-1, \ldots, 1\) do
            sum \(\leftarrow\) sum \(+A[i]\)
            if sum \(>\) opt then \(o p t \leftarrow\) sum
        return opt
    function MaximizeUpperHalf()
    opt \(_{\text {mid }} \leftarrow\) MaximizeLowerHalf ()\(+\) MaximizeUpperHalf()
    return \(\max \left(o p t_{l o}, o p t_{h i}, o p t_{\text {mid }}\right)\).
```

where $\bar{M}(j)$ is the maximum sum for subarrays of $A[1 . . j]$ that include $j$. Notice that the optimal subarray containing $A[n]$ is either $A[i . . n]$ for $i \leq n-1$ or exactly $[A[n]]$.

```
Algorithm 1.2.5 DynamicProgramming \((A)\)
    \(\bar{M} \leftarrow A[1]\)
    \(M \leftarrow \max (\bar{M}, 0)\)
    for \(i=2, \ldots, n\) do
        \(\bar{M} \leftarrow A[i]+\max (\bar{M}, 0)\)
        \(M \leftarrow \max (M, \bar{M})\)
    return \(M\)
```

which has runtime $\Theta(n)$. We cannot do better than this (proof beyond the scope of the course, but intuitively notice that we cannot find a max without knowing the entire array).

### 1.3 Recurrence Relations

Recall merge sort.
The recurrence relation is $T(n)= \begin{cases}T\left(\left\lceil\frac{n}{2}\right\rceil\right)+T\left(\left\lfloor\frac{n}{2}\right\rfloor\right)+\Theta(n) & n>1 \\ \Theta(1) & n=1\end{cases}$
If we let $c$ and $d$ be the constants, we get $T(n)= \begin{cases}T\left(\left\lceil\frac{n}{2}\right\rceil\right)+T\left(\left\lfloor\frac{n}{2}\right\rfloor\right)+c n & n>1 \\ d & n=1\end{cases}$
Equivalently, we can sloppily remove floors and ceilings to get $T(n)= \begin{cases}2 T\left(\frac{n}{2}\right)+c n & n>1 \\ d & n=1\end{cases}$
Construct now a recursion tree, assuming $n=2^{j}$. Notice that we will end up with $j$ layers where layer $i$ has $2^{i}$ nodes where each node takes $c n$ time (the last layer nodes take $d$ time).

Theorem 1.3.1 (master theorem)
Suppose $a \geq 1$ and $b>1$. Consider the recurrence

$$
T(n)=a T\left(\frac{n}{b}\right)+\Theta\left(n^{y}\right)
$$

in sloppy or exact form. Let $x=\log _{b}(a)$. Then,

$$
T(n)= \begin{cases}\Theta\left(n^{x}\right) & y<x \\ \Theta\left(n^{y} \log n\right) & y=x \\ \Theta\left(n^{y}\right) & y>x\end{cases}
$$

Proof. Let $a \geq 1$ and $b \geq 2$. Then, let $T(n)=a T\left(\frac{n}{b}\right)+c n^{y}$ and $T(1)=d$. Also, write for convenience $n=b^{j}$. We can now consider the recurrence tree.

The $i^{\text {th }}$ row in the tree (except the bottom) will have $a^{i}$ subproblems of size $n / b^{i}$ which each have $\operatorname{cost} c\left(n / b^{i}\right)^{y}=c n^{y} b^{-i y}$. The $j^{\text {th }}$ row will have $a^{j}$ nodes with cost $d$. Then,

$$
T(n)=d a^{j}+c n^{y} \sum_{i=0}^{j-1}\left(\frac{a}{b^{y}}\right)^{i}
$$

We know that $x=\log _{b} a$ which gives $b^{x}=a$. Assume $r=\frac{a}{b^{y}}=\frac{b^{x}}{b^{y}}=b^{x-y}$. Then, we have

$$
\begin{aligned}
d a^{\log _{b} n}+c n^{y} \sum_{i=0}^{j-1} r^{i} & =d n^{\log _{b} a}+c n^{y} \sum_{i=0}^{j-1} r^{i} \\
& =d n^{x}+c n^{y} \begin{cases}j & r=1 \\
\Theta(1) & r<1 \\
\frac{r^{j}-1}{r-1} \in \Theta\left(r^{j}\right) & r>1\end{cases} \\
& = \begin{cases}d n^{x}+c n^{y} \log _{b} n \in \Theta\left(n^{y} \log n\right) & x=y \\
d n^{x}+c^{\prime} n^{y} \in \Theta\left(n^{y}\right) & x<y \\
d n^{x}+c^{\prime \prime} n^{x} \in \Theta\left(n^{x}\right) & x>y\end{cases}
\end{aligned}
$$

noting that $r^{j}=r^{\log _{b} n}=n^{\log _{b} r}=n^{x-y}$, so in the latter case $c n^{y} \Theta\left(r^{j}\right) \in \Theta\left(n^{x}\right)$.

When $n^{x}$ dominates, we call it "heavy leaves". When $n^{y}$ dominates, we call it "heavy top". Otherwise, we call it "balanced".

## Chapter 2

## Divide and Conquer

In general, we want to:

- divide: split a problem into subproblems;
- conquer: solve the subproblems recursively; and
- combine: use subproblem results to derive problem result

This is possible when:

- the original problem is easily decomposable into subproblems;
- combining solutions is not costly; and
- subproblems are not overly unbalanced

### 2.1 Examples

Problem 2.1.1 (counting inversions)
Given an unsorted array $A[1 . . n]$, find the number of inversions in it, i.e., pairs $(i, j)$ such that $A[i]>A[j]$.

Example 2.1.2. Given $A=[1,5,2,6,3,8,7,4]$, we get $(2,3),(2,5),(2,8),(4,5),(4,8),(6,7)$, $(6,8)$, and $(7,8)$.

The naive algorithm checks all pairs and takes $\Theta\left(n^{2}\right)$ time. We can do better.
Let $c_{\ell}$ be the number of inversions in $A[1 . . n / 2], c_{r}$ be the number of inversions in $A[n / 2+1 . . n]$, and $c_{t}$ be the number of transverse inversions, i.e., inversions where $i$ is on the left and $j$ is on the right.

We can find $c_{\ell}$ and $c_{r}$ by recursion.
To find $c_{t}$, we must count the number of left indices greater than each right index. This can be done by sorting and then binary searching, since the binary search result index gives exactly what we want. The sort takes $O(n \log n)$ and each of the $n$ binary searches takes $O(\log n)$.

This gives us $T(n) \leq 2 T(n / 2)+O(n \log n)=O\left(n \log ^{2} n\right)$.
We can instead modify MergeSort and find $c_{t}$ using a modified Merge:

```
Algorithm 2.1.3 Modified \(\operatorname{Merge}(A[1 . . n])\) (additions in green)
Require: both halves of \(A\) are sorted
    copy \(A\) into a new array \(S ; c=0\)
    \(i \leftarrow 1 ; j \leftarrow n / 2+1\)
    for \(k \leftarrow 1, \ldots, n\) do
        if \(i>n / 2\) then \(A[k] \leftarrow S[j++]\)
        else if \(j>n\) then
            \(A[k] \leftarrow S[i++]\)
            \(c \leftarrow c+\frac{n}{2}\)
        else if \(S[i]<S[j]\) then
            \(A[k] \leftarrow S[i++]\)
            \(c \leftarrow c+j-\left(\frac{n}{2}+1\right)\)
        else \(A[k] \leftarrow S[j++]\)
```

Here, every time we merge in an element from the left, we add to $c$ the number of elements on the right which are greater than it. This will run in $\Theta(n \log n)$ time because the modified Merge is still $\Theta(n)$.

Problem 2.1.4 (polynomial multiplication)
Given $F=f_{0}+\cdots+f_{n-1} x^{n-1}$ and $G=g_{0}+\cdots+g_{n-1} x^{n-1}$, calculate $H=F G$.

The naive algorithm takes $\Theta\left(n^{2}\right)$ time to expand.
Notice that we can split $F=F_{0}+F_{1} x^{n / 2}$ and $G=G_{0}+G_{1} x^{n / 2}$. Then, we have $H=F_{0} G_{0}+$ $\left(F_{0} G_{1}+F_{1} G_{0}\right) x^{n / 2}+F_{1} G_{1} x^{n}$. If we divide and conquer, we make 4 recursive calls with size $n / 2$ and $\Theta(n)$ extra work for the additions.

However, $T(n)=4 T(n / 2)+\Theta(n) \in \Theta\left(n^{2}\right)$ which is not an improvement.
Lemma 2.1.5 (Karatsuba's identity)
$(x+y)(a+b)-x a-y b=x b+y a$

But if we already have $F_{0} G_{0}$ and $F_{1} G_{1}$, we can use Karatsuba's identity to instead calculate $\left(F_{0}+F_{1}\right)\left(G_{0}+G_{1}\right)-F_{0} G_{0}-F_{1} G_{1}=F_{0} G_{1}+F_{1} G_{0}$. That is, we will calculate:

$$
\begin{aligned}
H & =\left(F_{0}+F_{1} x^{n / 2}\right)\left(G_{0}+G_{1} x^{n / 2}\right) \\
& =F_{0} G_{0}+\left(\left(F_{0}+F_{1}\right)\left(G_{0}+G_{1}\right)-F_{0} G_{0}-F_{1} G_{1}\right) x^{n / 2}+F_{1} G_{1} x^{n}
\end{aligned}
$$

This means we only need to make 3 recursive calls instead of 4 .
Then, $T(n)=3 T(n / 2)+\Theta(n) \in \Theta\left(n^{\lg 3}\right)$ which is an improvement.

Based on this observation, Toom-Cook created a family of algorithms that for $k \geq 2$ make $2 k-1$ recursive calls in size $n / k$, i.e., $T(n) \in \Theta\left(n^{\log _{k}(2 k-1)}\right.$ ) which gets arbitrarily close to linear (but with increasingly massive constants).
If $F, G \in \mathbb{C}[x]$, then we can use FFT to get $T(n)=2 T(n / 2)+\Theta(n) \in \Theta(n \log n)$ time.

Problem 2.1.6 (matrix multiplication)
Given $A=\left[a_{i, j}\right] \in M_{n \times n}$ and $B=\left[b_{j, k}\right] \in M_{n \times n}$, calculate $C=A B$.

The naive algorithm takes inputs of size $\Theta\left(n^{2}\right)$ in $\Theta\left(n^{3}\right)$ time.
Consider instead breaking into block matrices: $A=\left(\begin{array}{l|l|l}A_{1,1} & A_{2,2} \\ \hline A_{2,1} & A_{2,2}\end{array}\right)$ and $B=\left(\begin{array}{l|l}B_{1,1} & B_{2,2} \\ \hline B_{2,1} & B_{2,2}\end{array}\right)$.
Then, $C=\left(\begin{array}{l|l}A_{1,1} B_{1,1}+A_{1,2} B_{2,1} & A_{1,1} B_{1,2}+A_{1,2} B_{2,2} \\ \hline A_{2,1} B_{1,1}+A_{2,2} B_{2,1} & A_{2,1} B_{1,2}+A_{2,2} B_{2,2}\end{array}\right)$
This makes 8 recursive calls of size $n / 2$ and $\Theta\left(n^{2}\right)$ additions, which resolves to $\Theta\left(n^{3}\right)$ (no improvement). However, due to Strassen, we can reduce this to 7 , giving $\Theta\left(n^{\lg 7}\right)$ time.
We can generalize to do $k$ multiplications of $\ell \times \ell$ matrices in $\Theta\left(n^{\log _{\ell} k}\right)$ time and $k$ multiplications of $\ell \times m$ by $m \times p$ in $\Theta\left(n^{3 \log _{\ell m_{p}} k}\right)$ time.

Problem 2.1.7 (closest pairs)
Given $n$ distinct points $\left(x_{i}, y_{i}\right)$, find a pair $(i, j)$ that minimizes the distance

$$
d_{i, j}=\sqrt{\left(x_{i}-x_{j}\right)^{2}+\left(y_{i}-y_{j}\right)^{2}}
$$

Equivalently, minimize $d_{i, j}^{2}=\left(x_{i}-x_{j}\right)^{2}+\left(y_{i}-y_{j}\right)^{2}$.

Separate the space of points into $L$ and $R$ halfspaces based on the median $x$ value. The closest pair is either entirely in $L$, entirely in $R$, or transverse.

We can recursively find minimum distances $\delta_{L}$ and $\delta_{R}$. Then, if we let $\delta=\min \left\{\delta_{L}, \delta_{R}\right\}$, any closer transverse points must be within $\delta$ units of the median $x$ value.

Now, if we start from the bottom point $P \in L$ by $y$-value in that band, we only have to compare $P$ with points $Q \in R$ with $y_{P} \leq y_{Q}<y_{P}+\delta$.

We can only have a maximum of 8 points inside the $2 \delta \times \delta$ rectangle of possible $Q$ points, because the points must be at least $\delta$ apart.

Therefore, we are doing $\Theta(1)$ work for each $P$, so we do $\Theta(n)$ work to find transverse pairs.
For this to work, we must first sort the points by $x$ and by $y$ (in $O(n \log n)$ time). We can find the median in $O(1)$ time. We split the sorted points in $O(n)$ time for the two recursive calls and find the $\delta$ band in $O(n)$ time. Again, it takes $O(n)$ time to find transverse pairs. Therefore, $T(n)=2 T(n / 2)+O(n)=O(n \log n)$.

Problem 2.1.8 (selection)
Given $A[0 . . n-1]$, find the entry that would be at index $k$ if $A$ were sorted.

Recall from CS 240 that selection by sorting takes $O(n \log n)$ time or $O(n)$ randomized expected time using QuickSelect $(A, k)$ :

```
Algorithm 2.1.9 QuickSelect \((A, k)\)
    \(p \leftarrow\) ChoosePivot \((A)\)
    \(i \leftarrow \operatorname{Partition}(A, p) \quad D i\) is the correct index of \(p\)
    if \(i=k\) then return \(A[i]\)
    else if \(i>k\) then return QuickSelect \((A[0 . . i-1], k)\)
    else return QuickSelect \((A[i+1 . . n-1], k-i-1)\)
```

Consider splitting $A$ into groups $G_{i}$ of size 5 . Then, find the medians $m_{i}$ of each group. We can choose the pivot $p$ as the median of medians:

Then, we are guaranteed to have $3 n / 10$ elements above and below $p=A[i]$, so the recursive calls to $A[0 . . i-1]$ and $A[i+1 . . n-1]$ have size at most $7 n / 10$ (with equality when $i$ is exactly $3 n / 10$ or $7 n / 10)$.

Therefore, $T(n) \leq T(n / 5)+T(7 n / 10)+O(n)$.

Lecture 5
(05/25)

Proof. Proceed by induction. Note that $T(n) \leq \begin{cases}O(1) & n<120 \\ T\left(\frac{n}{5}\right)+T\left(\frac{7}{10} n+6\right)+O(n) & n \geq 120\end{cases}$
We will show that $T(n) \leq c n$ for large enough $c$ and all $n>0$. We know that there exists a sufficiently large $c$ such that $T(n) \leq c n$ for $n<120$ because $T(n)$ is just $O(1) \subsetneq O(n)$.

Choose a constant $a$ to write $O(n)$ as an.

Suppose $T(m) \in O(m)$ for all $0<m<n$. Then,

$$
\begin{aligned}
T(n) & \leq \frac{c n}{5}+c\left(\frac{7 n}{10}+6\right)+a n \\
& \leq c \frac{n}{5}+c \frac{7 n}{10}+6 c+a n \\
& =9 c \frac{n}{10}+6 c+a n \\
& =c n+\left(-c \frac{n}{10}+6 c+a n\right)
\end{aligned}
$$

We can show that the latter term is non-positive:

$$
\begin{aligned}
-c \frac{n}{10}+6 c+a n \leq 0 & \Longleftrightarrow c\left(6-\frac{n}{10}\right)+a n \leq 0 \\
& \Longleftrightarrow c\left(6-\frac{n}{10}\right) \leq-a n \\
& \Longleftrightarrow c\left(\frac{n}{10}-6\right) \geq a n \\
& \Longleftrightarrow c \geq 10 a \frac{n}{n-60}
\end{aligned}
$$

Now, if $\frac{n}{n-60} \leq 2$, i.e., $n \geq 120$, then we can say that $c \geq 20 a$.
Therefore, we can say that $T(n) \leq c n$, i.e., $T(n) \in O(n)$.

Example 2.1.11. What does $T(n)=T\left(\frac{2}{3} n\right)+T\left(\frac{n}{3}\right)+n$ resolve to?

Solution. Notice that if we draw a tree, each layer sums to $n$ (this makes sense inductively since we pass $\frac{2}{3}$ of $n$ to the left and $\frac{1}{3}$ of $n$ to the right). There will be $O\left(\log _{3 / 2} n\right)$ layers in the tree, so it should resolve to $O(n \log n)$.

## Chapter 3

## Graph Algorithms

### 3.1 Graph Theory Review

Recall graph theory from MATH 239, specifically: ms

## Definition 3.1.1 (graph)

A graph $G$ is a pair $(V, E)$ where $V$ is a finite set of vertices and $E$ is a set of unordered pairs of distinct vertices, called edges. By convention, we write $n=|V|$ and $m=|E|$.

Now, we can define some structures on a graph:

Definition 3.1.2 (adjacency list)
An array $A[1 . . n]$ such that $A[v]$ is a linked list containing all edges connected to $v$. This contains $2 m$ list cells with total size $\Theta(n+m)$ but takes more than $O(1)$ time to test if an edge exists.

Definition 3.1.3 (adjacency matrix)
A matrix $M \in M_{n \times n}(\{0,1\})$ such that $M[v, w]=1$ if and only if $\{v, w\} \in E$. Size is $\Theta\left(n^{2}\right)$ but testing if an edge exists is $O(1)$.

Example 3.1.4. Given the graph

$1 \rightarrow 2 \rightarrow 5$
$2 \rightarrow 1 \rightarrow 3 \rightarrow 4 \rightarrow 5$
$3 \rightarrow 2 \rightarrow 4$
$4 \rightarrow 2 \rightarrow 3 \rightarrow 5$
$5 \rightarrow 1 \rightarrow 2 \rightarrow 4$
and the adjacency matrix is

$$
M=\left[\begin{array}{lllll}
0 & 1 & 0 & 0 & 1 \\
1 & 0 & 1 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 \\
0 & 1 & 1 & 0 & 1 \\
1 & 1 & 0 & 1 & 0
\end{array}\right]
$$

## Definition 3.1.5 (graph terminology)

We also recall some terms from MATH 239:

- A path is a sequence of vertices $v_{1}, \ldots, v_{k}$ such that $\left\{v_{i}, v_{i+1}\right\} \in E$ for all $i$. If a path from $v$ to $w$ exists, we write $v \rightsquigarrow w$.
- A connected graph has $v \rightsquigarrow w$ for all $v, w \in V$.
- A cycle is a path $v \rightsquigarrow v$ of length at least 3 with all elements pairwise distinct.
- A tree is a graph with no cycles.
- A rooted tree is a tree with a vertex chosen to be the root.
- A subgraph of $G=(V, E)$ is a graph $G^{\prime}=\left(V^{\prime}, E^{\prime}\right)$ where $V^{\prime} \subseteq V, E^{\prime} \subseteq E$, and $u, v \in V^{\prime}$ for all $u v \in E^{\prime}$.
- A connected component of $G$ is a connected subgraph of $G$ that is not a subset of any other connected subgraph.

### 3.2 Breadth-First Search

## Problem 3.2.1

Search a graph $G$ starting from a vertex $s$ in order of distance from $s$.

```
Algorithm 3.2.2 \(\operatorname{BFS}(G, s)\)
    let \(Q\) be an empty queue
    let visited be a boolean array of size \(n\) with all entries set to \(\perp\)
    Enqueue ( \(s, Q\) )
    visited \([s] \leftarrow \top\)
    while \(Q\) is not empty do
        \(v \leftarrow \operatorname{DEQUEUE}(Q)\)
        for \(w\) neighbours of \(v\) do
            if visited \([w]=\perp\) then
                Enqueue \((w, Q)\)
                visited \([w] \leftarrow \top\)
```

Each vertex is enqueued at most once and dequeued at most once, which has cost $O(n)$. Therefore, each adjacency list is read at most once. The cost for the for loop is $O\left(\sum \operatorname{deg} v\right)=O(m)$ by the Handshaking Lemma.

Therefore, the total cost of BFS is $O(n+m)$.

Lemma 3.2.3
$\operatorname{visited}[v]$ is true for some vertex $v$ if and only if $s \rightsquigarrow v$ in $G$.

Proof. Let $s=v_{0}, \ldots, v_{K}$ be the vertices with visited $v_{i}=\top$, in order of discovery. By induction, we show that $s \rightsquigarrow v_{i}$.

For $i=0, v_{0}=s$, so trivially $s \rightsquigarrow s$.
Otherwise, suppose $s \rightsquigarrow v_{j}$ for all $j<i$. We are currently in the for loop for some vertex $w$ already visited. Therefore, by assumption, $s \rightsquigarrow w$. But since $v_{i}$ is a neighbour of $w, s \rightsquigarrow v_{i}$.

Exercise 3.2.4. For a connected graph, $m \geq n-1$.

Proof. Recall from MATH 239 that if a graph $G$ is connected, then it has a spanning tree $T$. The spanning tree of $n$ vertices has exactly $n-1$ edges. Then, since the spanning tree is a subgraph of $G, m \geq|E(T)|=n-1$, as desired.

### 3.3 Shortest Path by BFS

## Problem 3.3.1

What is the shortest path from $s$ to $v$ in $G$ ?

Consider now how we can keep track of parents (predecessors) and levels (depths):

```
Algorithm 3.3.2 \(\operatorname{BFS}(G, s)\) with parents and levels
    let \(Q\) be an empty queue
    let parent be an array of size \(n\) with all entries set to \(\perp\)
    let level be an array of size \(n\) with all entries set to \(\infty\)
    EnQueue \((s, Q)\)
    parent \([s] \leftarrow s\)
    level \([s] \leftarrow 0\)
    while \(Q\) is not empty do
        \(v \leftarrow \operatorname{DEQUEUE}(Q)\)
        for \(w\) neighbours of \(v\) do
            if parent \([w]=\perp\) then
                    EnQueue \((w, Q)\)
                    parent \([w] \leftarrow v\)
                    \(\operatorname{level}[w] \leftarrow\) level \([v]+1\)
```

We can define a BFS tree $T$ as the subgraph of $G$ made of all $w$ such that parent $[w] \neq \perp$ and all edges $\{w$, parent $[w]\}$ between those vertices.

Claim 3.3.3. The BFS tree $T$ is in fact a tree.

Proof. Proceed by induction on the vertices for which parent $[v]$ is not $\perp$.
When we set parent $[s] \leftarrow s$, we have one vertex and no edges.
Suppose $T$ is a tree and we are adding parent $[w] \leftarrow v$. Then, $v$ must have already been in $T$ because it came from $Q$, so we are extending $T$ by adding (1) the vertex $w$ and (2) the edge $\{v, w\}$. This does not create a cycle because parent $[w]=\perp$, so $T$ remains a tree.

Therefore, by induction, at the end of BFS, $T$ is a tree.

Claim 3.3.4. The levels in the queue $Q$ are non-decreasing.

Proof. Exercise (TODO).

Claim 3.3.5. For all vertices $u$ and $v$, if there is an edge $\{u, v\}$, then level $[v] \leq \operatorname{level}[u]+1$.

Proof. Suppose that $u$ and $v$ are adjacent and visited.
If we dequeue $v$ before $u$, then level $[v] \leq \operatorname{level}[u]+1$ by Claim 3.3.4.
If $u$ is dequeued before $v$, then the parent of $v$ is either $u$ or something else before $u$. This is because while visiting $u$, we must either have enqueued $v$ or already visited $v$. Therefore, $v$ 's parent must be at or before $u$. Then, by Claim 3.3.4, level $[$ parent $[v]] \leq$ level $[u]$.

That is, level $[v]=\operatorname{level}[$ parent $[v]]+1 \leq \operatorname{level}[u]+1$.

## Lemma 3.3.6

For all $v$ in $G$, there is a path $s \rightsquigarrow v$ in $G$ if and only if there is a path $s \rightsquigarrow v$ in $T$. If so, the path in $T$ is a shortest path and level $[v]$ is the distance from $s$ to $t$.

Proof. By Lemma 3.2.3, $s \rightsquigarrow_{G} v$ if and only if $v$ is visited. That is, all such $v$ are in $T$. But $T$ is connected as a tree, therefore $s \rightsquigarrow_{G} v \Leftrightarrow s \rightsquigarrow_{T} v$.

Let $\delta$ be the distance from $s$ to $v$. We must show level $[v] \leq \delta$ and $\delta \leq$ level $[v]$.
Trivially, $\delta \leq \operatorname{level}[v]$ because level $[v]$ is the length of the path $s \rightsquigarrow_{T} v$.
We will prove by induction that for all $i$, if there is a path of length $i$ from $s$ to $v$, then level $[v] \leq i$. For the base case $i=0$, there are no such paths.

Suppose this is true for $i-1$, and consider a path $P=s \cdots u v$ with length $i$. Then, we can decompose $P$ as $P^{\prime}=s \cdots u$ and $u v$. But $P^{\prime}$ has length $i-1$, so level $[u] \leq i-1$. Then, by Claim 3.3.5, level $[v] \leq \operatorname{level}[u]+1 \leq i$.

Therefore, since this is true for all $i$, it is true for $i=\delta$.
Finally, we have that $\delta=$ level $[v]$ and $s \rightsquigarrow_{T} v$ is a shortest path.

### 3.4 Bipartiteness by BFS

Definition 3.4.1 (bipartite)
A graph $G=(V, E)$ is bipartite if there exists a partition $U_{1} \sqcup U_{2}=V$ such that for every $u v \in E, u \in U_{1}$ and $v \in U_{2}$ (or vice versa).

Problem 3.4.2
Is $G$ bipartite?

## Lemma 3.4.3

Suppose $G$ is connected and we run $\operatorname{BFS}(G, s)$ for some $s$. Let $V_{1}$ and $V_{2}$ be vertex sets with odd and even level respectively. Then, $G$ is bipartite if and only if all edges have one end in $V_{1}$ and one end in $V_{2}$.

Proof. Suppose all edges have one end in $V_{1}$ and one end in $V_{2}$. Then, $G$ is bipartite by definition.

Suppose $G$ has bipartition $\left(W_{1}, W_{2}\right)$. Then, wlog say that $s \in W_{2}$. Since $s \rightsquigarrow v$ for all $v \in V$ and $W_{2}=V_{2}$.

This is nice because we can test in $O(m)$ time.

### 3.5 Depth-First Search

Analogous to BFS, but we use a stack (implicitly with recursion, or explicitly with a stack data structure) to follow neighbours until we cannot.

```
Algorithm 3.5.1 DFS(G)
Require: \(G\) is a graph on \(n\) vertices given by adjacency lists
    visited \(\leftarrow\) array of size \(n\) initialized to \(\perp\)
    procedure EXPLORE ( \(v\) )
        visited \([v] \leftarrow \top\)
        for \(w\) neighbour of \(v\) do
            if visited \([v]=\perp\) then
                EXPLORE( \(v\) )
    for \(v \in G\) do
        if visited \([v]=\perp\) then
            EXPLORE ( \(v\) )
```

Lemma 3.5.2 (white path lemma)
When we start exploring $v$, any $w$ connected to $v$ by an unvisited path will be visited during EXPLORE $(v)$.

Proof. Let $v_{0}=v \cdots v_{k}=w$ be a path $v \rightsquigarrow w$ with $v_{1}, \ldots, v_{k}$ all not visited. We prove all $v_{i}$ are visited before EXPLORE $(v)$ is finished.
Obviously holds for $i=0$. Suppose it holds for $i<k$. When we visit $v_{i}$, $\operatorname{EXPlore}(v)$ is not finished and $v_{i+1}$ is one of the neighbours.

If visited $\left[v_{i+1}\right]$ is already true (because $v \rightsquigarrow v_{i+1}$ by some other path), we are done. Otherwise, we are going to visit it now, which is before $\operatorname{Explore}(v)$ is finished.

Therefore, $v_{i+1}$ is visited during $\operatorname{Explore}(v)$, as desired.

Corollary 3.5.3. After we call Explore at $v_{1}, \ldots, v_{k}$, we have visited exactly the connected components containing $v_{1}, \ldots, v_{k}$.

Note: we cannot find shortest paths using a DFS tree without customization. For example, the DFS tree for a cycle will be a path even though the root and leaf are adjacent.

The runtime is still $O(n+m)$.
Definition 3.5.4
Let $T_{1}, \ldots, T_{k}$ be a DFS forest with vertices $u$ and $v$. Then, $u$ is an ancestor of $v$ if $u, v \in T_{i}$ for some $i$ and $u$ is on the path from the root of $T_{i}$ to $v$. Equivalently, we write that $v$ is a descendant of $u$.

Lemma 3.5.5 (key property)
All edges in $G$ connect a vertex to one of its descendants or ancestors.

Proof. Let $\{v, w\}$ be an edge and suppose WLOG we visit $v$ first.
Then, when we visit $v,(v, w)$ is an unvisited path $v \rightsquigarrow w$, so by the white path lemma, $w$ must become a descendant of $v$.

Definition 3.5.6 (back edge)
An edge in $G$ connecting an ancestor to a descendant which is not in the BFS forest.

Corollary 3.5.7. All edges are either tree edges or back edges.

Proof. Equivalent statement of the 3.5.5.

We can extend DFS with start and finish arrays:

```
Algorithm 3.5.8 \(\mathrm{DFS}(G)\) with timing
Require: \(G\) is a graph on \(n\) vertices given by adjacency lists
    visited \(\leftarrow\) array of size \(n\) initialized to \(\perp\)
    start, finish \(\leftarrow\) array of size \(n\)
    \(t \leftarrow 1\)
    procedure EXPLORE \((v)\)
        visited \([v] \leftarrow \top\)
        \(\operatorname{start}[v] \leftarrow t ; t++\)
        for \(w\) neighbour of \(v\) do
            if visited \([v]=\perp\) then
                EXPLORE \((v)\)
        finish \([v] \leftarrow t ; t++\)
    for \(v \in G\) do
        if visited \([v]=\perp\) then
            EXPLORE \((v)\)
```

For example, we can draw a graph with $[\operatorname{start}[v]$, finish $[v]]$ labelled:

Notice that the intervals shrink with depth and follow a structure similar to the well-formed parenthesis problem. We can in fact prove:

Lemma 3.5.9 (parentheses theorem)
If start $[u]<\operatorname{start}[v]$, then either finish $[u]<\operatorname{start}[v]$ or finish $[u]<$ finish $[v]$.

Proof. If start $[u]<\operatorname{start}[v]$, we push $v$ on the stack while $u$ is still there, so we pop $v$ before we pop $u$ since stacks are FIFO.

### 3.6 Cut Vertices by DFS

We define a cut vertex analogous to a bridge edge from MATH 239.

## Definition 3.6.1 (cut vertex)

Given a connected graph $G$, a vertex $v \in V(G)$ is a cut vertex (or articulation point) if removing $v$ and its edges makes $G$ disconnected.

Example 3.6.2.

Problem 3.6.3
Which of the vertices in $G$ are cut vertices?

Consider a rooted DFS tree $T$ with known parent and level.

## Proposition 3.6.4

The root $s$ is a cut vertex if and only if it has more than one child.

Proof. Suppose $s$ has one child $v$. Then, $T-s$ is a rooted DFS tree with root $v$ (i.e., it remains connected).

Suppose $s$ has subtrees $S_{1}, \ldots, S_{k}$. Let $u \in S_{i}$ and $v \in S_{j}$ for $i \neq j$. Then, there does not exist a path $u \rightsquigarrow v$ in $T-s$ by the key property since it would involve a non-tree, non-back cross edge. Therefore, the subtrees are disconnected in $T-s$.

Proposition 3.6.5
Let $a(v)=\min \{$ level $[w]: v w \in E(G)\}$ and $m(v)=\min \{a(w): w$ descendant of $v\}$. Any non-root vertex $v$ is a cut vertex if and only if it has a child $w$ with $m(w) \geq$ level $[v]$.

Proof. Let $w$ be a child of $v$ with subtrees $T_{w}$ and $T_{v}$, respectively.
Suppose $m(w)<$ level $[v]$ and we have removed $v$. Then, there is a vertex $w^{\prime}$ in $T_{w}$ to some vertex $v^{\prime}$ above $v$. That is, for any vertex $u \in V\left(T_{w}\right)$, we have that $u \rightsquigarrow w \rightsquigarrow w^{\prime} \rightsquigarrow v^{\prime} \rightsquigarrow s$ and $T_{w}$ is still connected.

Therefore, for $v$ to be a cut vertex, we must have $m(w) \geq$ level $[v]$.
Suppose $m(w) \geq$ level $[v]$. Then, by the key property, all edges from $T_{w}$ end in $T_{v}$. They are either the tree edge $v w$ or a back edge going to an ancestor at or below $v$. Therefore, removing $v$ will cause $T_{w}$ to be disconnected and $v$ is a cut vertex.

Therefore, we can solve the cut vertex problem by calculating $m(v)$ for every vertex.
We can compute $a(v)$ in $O(\operatorname{deg} v)$. Notice that if $v$ has children $w_{1}, \ldots, w_{k}$, then $m(v)=\min \left\{a(v), m\left(w_{1}\right), \ldots, m\left(w_{k}\right)\right\}$ Then, if we have the $m$ of the children, we get $m(v)$ in $O(\operatorname{deg} v)$.

By traversing the DFS tree, we get every $m(v)$ in $O(n+m)=O(m)$ (since $G$ connected). Then, we can test the cut vertex condition for each vertex $v$ and each of its children in $O(\operatorname{deg} v)$.
Therefore, we can test all vertices in $O(m)$ time.

```
Algorithm 3.6.6 FindCutVertices( \(G, s\) )
    \(T \leftarrow \operatorname{DFS}(G, s) \quad D\) DFS tree for \(G\) with root and level
    \(a, m \leftarrow\) arrays of size \(|V(G)|\) initialized to \(\infty\)
    cut \(\leftarrow\) array of size \(|V(G)|\) initialized to \(\perp\)
    procedure Explore \((v)\)
        for \(w\) child of \(v\) do
            \(a[v] \leftarrow \min \{a[v]\), level \([w]\}\)
            EXPLORE(w)
            \(m[v] \leftarrow \min \{m[v], a[w]\}\)
        \(m[v] \leftarrow \min \{a[v], m[v]\}\)
        for \(w\) child of \(v\) do
            if \(m[w] \geq T\).level \([v]\) then \(\operatorname{cut}[v] \leftarrow \top\)
    Explore(T.root)
```

### 3.7 Directed Graphs

We can define a directed graph similar to an ordinary graph:

## Definition 3.7.1 (directed graph)

A graph $G=(V, E)$ where edges are ordered pairs $(u, v)$.
If $G$ has no cycles, it is a directed acyclic graph (DAG).

Note that we allow loops $(v, v)$. Paths and cycles have the ordinary meaning.

Definition 3.7.2 (topological ordering)
An ordering $<$ of $V$ in a DAG such that $(a, b) \in E$ implies $a<b$.

## Proposition 3.7.3

Lecture 9
(06/08)

A directed graph is acyclic if and only if there is a topological ordering on it.

Proof. The backwards direction is clear.
Assume we have a DAG. There exists at least one vertex with in-degree 0 , because otherwise there would be a cycle. We can inductively remove the vertex with in-degree 0 to get a topological ordering.

In fact, if run DFS and we order $V$ with the ordering $v<w \Leftrightarrow$ finish $[w]<$ finish $[v]$, then we can show that $<$ is a topological order.

Suppose that $(v, w) \in E$.
If we discover $v$ before $w$, then $w$ is a descendant of $v$ by the white path lemma so we must finish exploring it before we finish $v$.

Otherwise, if we discover $w$ before $v$, then there cannot exist a path $w \rightsquigarrow v$ because otherwise $w \rightsquigarrow v w$ is a cycle. Therefore, finish $[w]<\operatorname{start}[v]<\operatorname{finish}[v]$.
Therefore, $<$ is a topological order whose existence is necessary and sufficient for a DAG.

Definition 3.7.4 (strong connectivity)
A directed graph $G$ is strongly connected if for all $v$ and $w$ in $G$, there is a path $v \rightsquigarrow w$ (and $w \rightsquigarrow v$ )

Corollary 3.7.5. $G$ is strongly connected if and only if there exists $s$ such that for all $w$ there exist paths $s \rightsquigarrow w$ and $w \rightsquigarrow s$.

Proof. The forwards direction is trivial. In the backwards direction, notice that for any two vertices $v$ and $w$, we have $v \rightsquigarrow s \rightsquigarrow w$ and $w \rightsquigarrow s \rightsquigarrow v$.

Problem 3.7.6
How can we test if a graph is strongly connected?

Solution. Call Explore twice, starting from the same vertex $s$. On the second run, reverse all the edges. Then, if every vertex $v$ is explored in both runs, we know that $s \rightsquigarrow v$ and $v \rightsquigarrow s$, i.e., the graph is strongly connected.

We can reverse the edges using an adjacency list in $O(n+m)$ time, so this algorithm runs in $O(n+m)$ time.

## Proposition 3.7.7

Contracting the strongly connected components of a directed graph forms a DAG.

Proof. Suppose not. Then there exists a cycle of strongly connected components. However, this means that any vertex from any of these can be reached from any other. Therefore, the strongly connected component is not maximal.

```
Problem 3.7.8
What are the strongly connected components and their respective DAG?
```

Lecture 10

This has time complexity $O(n+m)$.

Proposition 3.7.10
For any vertices $v$ and $w$, TFAE: $v$ and $w$ are in the same SCC ; and $v$ and $w$ are in the same DFS tree of $G^{\top}$ (sorted by decreasing finish time).

```
Algorithm 3.7.9 Kosaraju's algorithm for strongly connected components
    procedure \(\operatorname{SCC}(G)\)
        run \(\operatorname{DFS}(G)\) augmented with finish times
        sort the vertices by decreasing finish time
        run \(\operatorname{DFS}\left(G^{\top}\right)\)
        return the trees in the DFS forest of \(G^{\top}\)
```

Proof. Suppose $v, w \in C \in S C C(G)$ and let $s$ be the first vertex visited in $C$. Then, $s \rightsquigarrow v$ within $C$ and the path is white when visiting $s$ by supposition. By the white path lemma, $v$ will be in the DFS tree. Likewise for $w$.

Suppose $v$ and $w$ are in a DFS tree $T$ for $G^{\top}$ rooted at $s$. That is, among the vertices in $T, s$ has the highest finish time. Let $t \in T$. As a descendent, $s \rightsquigarrow_{G^{\top}} t$, so $t \rightsquigarrow_{G} s$.

Claim that $t$ descends from $s$ in $G$, so we get a path $s \rightsquigarrow_{G} t$.
Proceed by structural induction on $t$ and its children. Let $u$ be a child of $t$ in T. Suppose start $[s] \leq$ $\operatorname{start}[t]<$ finish $[t] \leq$ finish $[s]$. Since finish $[u]<$ finish $[s]$, we have by the parentheses theorem that either $[s(u)]$ or $(u)[s]$. But the second option is impossible because if $t u \in E(T) \subseteq E\left(G^{\top}\right)$, then $u t \in E(G)$, which means that $u \rightsquigarrow t$ and by the white path lemma, $t$ should be a descendant of $u$, not $s$. Therefore, $u$ is a descendant of $s$, as desired.

Finally, because $s \rightsquigarrow_{G} t$ and $t \rightsquigarrow_{G} s, t$ is in the strongly connected component of $s$.

Problem 3.7.11
Does a graph $G$ contain a Hamiltonian path (i.e., a path $P$ with $P(V)=V$ )?

For an undirected graph $G$, this is one of the canonical NP-complete problems.
For a DAG $G$, we can do this in linear time with a topological ordering.

## Proposition 3.7.12

A DAG $G$ has a Hamiltonian path if and only if it has a topological ordering $v_{1}<\cdots<v_{k}$ such that $v_{i} v_{i+1} \in E(G)$ for all $i$.

Proof. Let $G$ have a Hamiltonian path $P=v_{1} \cdots v_{k}$. Define an ordering $v_{1}<\cdots<v_{k}$. Suppose $v_{i} v_{j} \in E(G)$. If $i>j$, then $v_{i} v_{j} v_{j+1} \cdots v_{i}$ is a cycle. However, $G$ is a DAG, so we must have $i<j$. Therefore, $<$ is a topological ordering as desired.

Suppose $G$ has a topological ordering $v_{1}<\cdots<v_{k}$ with $v_{i} v_{i+1} \in E(G)$ for all $i$. Then, we immediately get a Hamiltonian path given by $v_{1} \cdots v_{k}$.

## Chapter 4

## Greedy Algorithms

### 4.1 Introduction

Suppose we are solving a combinatorial optimization problem, i.e., a problem with a large (but finite) domain $\mathcal{D}$ such that we are trying to find an optimal solution $E \in \mathcal{D}$ that maximizes/minimizes some sort of cost function.

We will build $E$ step-by-step by taking the locally best solution. Usually, it is very hard to prove correctness/optimality but easy to find a counterexample.

For example, recall the Huffman encoding from CS 240 . We build the binary code tree by joining trees with the least frequencies. This actually minimizes the length of the encoding.

### 4.2 Basic Greedy Examples

Problem 4.2.1 (interval scheduling)
Suppose we have $n$ intervals $\left[s_{i}, f_{i}\right]$. What is the subset of disjoint intervals with maximum length?

We can show that a few naive greedy algorithms are wrong by drawing counterexamples:

- Choose $\min _{i} s_{i}: \longrightarrow \quad-\quad-\quad-$
- Choose $\min _{i}\left\{f_{i}-s_{i}\right\}$ : $\qquad$
- Choose minimum conflicts:

However, we can prove that the greedy algorithm taking the earliest finish time is optimal.

```
Algorithm 4.2.2 IntervalScheduling \(\left(I=\left[\left[s_{1}, f_{1}\right], \ldots,\left[s_{n}, f_{n}\right]\right]\right)\)
    \(S \leftarrow \varnothing\)
    \(I \leftarrow\) sort \(I\) by finish time
    for \(\left[s_{i}, f_{i}\right] \in I\) do
        if \(\left[s_{i}, f_{i}\right]\) has no conflicts in \(S\) then
            \(S \leftarrow S \cup\left\{\left[s_{i}, f_{i}\right]\right\}\)
```

## Proposition 4.2.3

Suppose $O$ is optimal. Then, $|S|=|O|$ where $S$ is generated by Algorithm 4.2.2.

Proof. Let $i_{1}, \ldots, i_{k}$ be the intervals in $S$ ordered by their addition and likewise $j_{1}, \ldots, j_{m}$ be the intervals in $O$ ordered by increasing finish time.

We prove the claim that for all $r \leq k, f_{i_{r}} \leq f_{j_{r}}$. Proceed by induction on $r$.
For $r=1$ this is true since $i_{1}$ is the interval with the earliest finish time.
Suppose $r>1$ and it is true for $r-1$. Then, $f_{i_{r-1}} \leq f_{j_{r-1}}$ by assumption and $f_{j_{r-1}}<s_{j_{r}}$ by the order we set on $O$. Therefore, $f_{i_{r-1}}<s_{j_{r}}$.

That is, at the time the greedy algorithm chose $i_{r-1}, j_{r}$ was an option. Since the greedy algorithm picks the earliest finish time, $f_{i_{r}} \leq f_{j_{r}}$.

Now, suppose for a contradiction that $S$ is not optimal, i.e., $|S|<|O|$. Then, there must be a $j_{k+1}$. But by the above claim, $f_{i_{k}} \leq f_{j_{k}}<s_{j_{k+1}}$. This means $j_{k+1}$ was an option for the greedy algorithm, so it would not have stopped at $i_{k}$ and instead added $j_{k+1}$.

Therefore, $S$ must be optimal.
We call proofs of this kind, i.e., contradicting that greedy could not have chosen an optimal solution, greedy stays ahead.

We can also greedily solve a similar problem:

Problem 4.2.4 (interval colouring)
Suppose we have $n$ intervals $\left[s_{i}, f_{i}\right]$. Use the minimum number of colours to colour the intervals, so that each interval gets one colour and any overlapping intervals get different colours.

Consider the algorithm:

```
Algorithm 4.2.5 IntervalColouring \(\left(I=\left[\left[s_{1}, f_{1}\right], \ldots,\left[s_{n}, f_{n}\right]\right]\right)\)
    \(c \leftarrow\) empty colouring
    \(I \leftarrow\) sort \(I\) by start time
    for \(\left[s_{i}, f_{i}\right] \in I\) do
        \(c(i) \leftarrow\) minimum \(c\) such that there are no conflicts
```

which we do not bother analyzing the time complexity of. We show correctness:

Proposition 4.2.6
Suppose that Algorithm 4.2.5 uses $k$ colours. There is no way to colour $I$ with $k-1$ colours.

Proof. Suppose interval $\ell$ is the first to use $k$. Then, the algorithm must have found $k-1$ overlapping intervals with colours $1, \ldots, k-1$. Let these be intervals $i_{1}, \ldots, i_{k-1}$. By the initial sorting, we have $s_{i_{j}}<s_{\ell}$ for $j=1, \ldots, k-1$. Also, since they overlap, we have $f_{i_{j}}>f_{\ell}$. Therefore, $s_{\ell}$ is a point with $k$ intervals, meaning that it is impossible to colour with $k-1$ colours.

Problem 4.2.7 (minimize total completion time)
Suppose we have $n$ jobs each requiring processing time $p_{i}$, and we are adding one job each step (e.g., the first step runs just one job, the fifth step runs five jobs, the last step runs all jobs). Order the jobs such that the total processing time is minimized.

The setup is a bit weird, so we can construct an example.
Example 4.2.8. For $n=5$ and $\mathbf{p}=[2,8,1,10,5]$, we can construct tables to find the total processing time if we do not order the jobs and if we order the jobs by increasing processing time:

| 2 | 8 | 1 | 10 | 5 | $\Sigma$ |  | 1 | 2 | 5 | 8 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\Sigma$ |  |  |  |  |  |  |  |  |  |  |  |
| 2 | 2 | 2 | 2 | 2 | 10 |  | 1 | 1 | 1 | 1 | 5 |
|  | 8 | 8 | 8 | 8 | 24 |  | 2 | 2 | 2 | 2 | 8 |
|  |  | 1 | 1 | 1 | 3 |  |  | 5 | 5 | 5 | 15 |
|  |  |  | 10 | 10 | 20 |  |  |  | 8 | 8 | 16 |
|  |  |  |  | 5 | 5 |  |  |  |  |  |  |
| 2 | 10 | 11 | 21 | 26 | 70 |  |  |  |  | 10 | 10 |
|  | 1 | 3 | 8 | 16 | 26 | 54 |  |  |  |  |  |

to find that the total processing times are 70 and 54 , respectively.

## Proposition 4.2.9

The total processing time is minimized when $e(i)$ is a permutation of $[n]$ such that $\left(p_{e(i)}\right)$ is non-decreasing.

Proof. Suppose there is an optimal permutation $e$ that is not non-decreasing. That is, there exists an $i$ such that $p_{e(i)}>p_{e(i+1)}$.
The total processing time is:

| $e(1)$ | $e(2)$ | $\ldots$ | $e(i)$ | $e(i+1)$ | $\ldots$ | $e(n)$ | $\Sigma$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $p_{e(1)}$ | $p_{e(1)}$ |  | $p_{e(1)}$ | $p_{e(1)}$ |  | $p_{e(1)}$ | $n p_{e(1)}$ |
|  | $p_{e(2)}$ |  | $p_{e(2)}$ | $p_{e(2)}$ |  | $p_{e(2)}$ | $(n-1) p_{e(2)}$ |
|  |  |  | $\vdots$ | $\vdots$ |  | $\vdots$ | $\vdots$ |
|  |  |  | $p_{e(i)}$ | $p_{e(i)}$ |  | $p_{e(i)}$ | $(n-i+1) p_{e(i)}$ |
|  |  |  |  | $p_{e(i+1)}$ |  | $p_{e(i+1)}$ | $(n-i) p_{e(i+1)}$ |
|  |  |  |  |  |  | $\vdots$ | $\vdots$ |
|  |  |  |  |  |  | $p_{e(n)}$ | $p_{e(n)}$ |

Suppose we swap $e(i)$ and $e(i+1)$. Then, we have removed one copy of $p_{e(i)}$ and added one copy of $p_{e(i+1)}$. But by assumption, $p_{e(i+1)}-p_{e(i)}<0$, so this swap decreases the total processing time, and the solution was not optimal.

### 4.3 Shortest Paths: Dijkstra's Algorithm

Recall that we can define a weight function on a graph.

Definition 4.3.1 (weight function)
Given a graph $G=(V, E)$, a function $w: E \rightarrow \mathbb{R}$. We call $(G, w)$ a weighted graph.
Then, we define the weight for a path $P=v_{0} \cdots v_{k}$ by $w(P)=\sum_{i=1}^{k} w\left(v_{i-1} v_{i}\right)$.

Remark 4.3.2. A shortest path exists in any directed weighted graph with no negative-weight cycles.

Problem 4.3.3 (single-source shortest path)
Given $G=(V, E)$ with weight $w: E \rightarrow \mathbb{R}_{\geq 0}$ and a source $s \in V$, find a shortest path from $s$ to each $v \in V$.

We denote the length of the shortest path $s \rightsquigarrow v$ by $\delta(s, v)$.
Remark 4.3.4. If $v_{0} \cdots v_{k}$ is a shortest path from $v_{0}$ to $v_{k}$, then $v_{0} \cdots v_{i}$ is a shortest path from $v_{0}$ to $v_{i}$ for all $0 \leq i \leq k$.

Proof. Suppose not. Then, use the shorter path to get to $v_{i}$ and continue onward to $v_{k}$ to get a shorter path to $v_{k}$.

Dijkstra's algorithm is built on this observation.
For each vertex, we maintain an estimate of the distance $d[v]$ and a predecessor in that path estimate $\pi[v]$. We start with all vertices in a set $Q$ and pop vertices one at a time in order of $d$, adding them to a set $C$. When a vertex moves from $Q$ to $C$, update the distance estimates and predecessors of its neighbours.

```
Algorithm 4.3.5 DiJkstra( \(G, w, s\) )
    for each vertex \(v \in V\) do
        \(d[v] \leftarrow \infty\)
        \(\pi[v] \leftarrow \perp\)
    \(d[s] \leftarrow 0\)
    \(C \leftarrow \varnothing\)
    \(Q \leftarrow V\)
    while \(Q \neq \varnothing\) do
        \(u \leftarrow \operatorname{ExtractMin}(Q)\)
        \(C \leftarrow C \cup\{u\}\)
        for neighbours \(v \in \operatorname{Adj}[u]\) do
            if \(d[v]>d[u]+w(u v)\) then
                \(d[v]=d[u]+w(u v)\)
                \(\pi[v]=u\)
```

Notice that we implement $Q$ and $C$ as heaps since then we get time complexity $O(|V| \log |V|+$ $|E| \log |V|$ ) (for the extractions and the updates, respectively) instead of $O\left(|V|^{2}+|E|\right)$ with arrays.

Claim now that Dijkstra's is correct. Proceed by a greedy stays ahead proof.
Lecture 14 (06/27)

Proposition 4.3.6
For each vertex $v \in V, d[v]=\delta(s, v)$ at the time $v$ is added to $C$.

Proof. Suppose for a contradiction that $u \in V$ is the first vertex for which $d[u] \neq \delta(s, u)$ when it is added to $C$. Denote the iteration when $u$ is added to $C$ as time $t$.

Let $P$ be a shortest path $s \rightsquigarrow u$. Since $s \in C$ and $P \in V-C$, there exists a pair of vertices $x \in C$ and $y \in V-C$ with $x y \in P$. We claim that at time $t, d[y]=\delta(s, y)$.

Since $u$ is the first vertex with $d[u] \neq \delta(s, u)$, for all vertices $w$ in $C$ at time $t, d[w]=\delta(s, w)$. In particular, $d[x]=\delta(s, x)$. When $x$ was added to $C$, the edge $x y$ was considered. By Remark 4.3.4, since $P$ is a shortest path, the parts from $s$ to $x$ and $y$ are also shortest paths. Therefore, $\delta(s, y)=$ $d[x]+w(x, y)$ which is exactly what $d[y]$ is set to during that iteration.

However, we can also say that $d[y]=\delta(s, y) \leq \delta(s, u) \leq d[u]$. But at time $t$, Dijkstra's chose $u$ from the min-heap, so we must have $d[u] \leq d[y]$.

Therefore, $d[y]=d[u]$ so we must have tight $d[y]=\delta(s, y)=\delta(s, u)=d[u]$, which is our contradiction.

### 4.4 Minimum Spanning Trees: Kruskal's Algorithm

Recall again some MATH 239 content:

Lecture 15 (06/29)

Definition 4.4.1 (spanning tree in $G$ )
Given a connected graph $G=(V, E)$, a tree $T=(V, A)$ where $A \subseteq E$.

Suppose we have a weighted graph. Then,

Problem 4.4.2 (minimal spanning tree)
Given a connected graph $G$ with edge weights $w$, what is the spanning tree with minimal weight $w(T)=\sum_{e \in A} w(e)$ ?

Recall that a tree is a graph with no cycles. Kruskal's algorithm greedily selects the lowest-weight edge available that does not create a cycle:

```
Algorithm 4.4.3 GreedyMST( \(G\) )
    \(A \leftarrow\) empty graph
    sort edges by increasing weight
    for \(e \in E\) do
        if \(e\) does not create a cycle in \(A\) then
                append \(e\) to \(A\)
```

Now, we prove that this indeed works.
Claim 4.4.4. Let $G=(V, E)$ be a connected graph and $A \subseteq E$. If ( $V, A$ ) has no cycles and $|A|<n-1$, then there is always an edge $e \in E-A$ such that $(V, A \cup\{e\})$ still has no cycles.

Proof. In any graph, $|V|-c \leq|E|$ where $c$ is the number of components $C_{i}=\left(V_{i}, E_{i}\right)$ in $(V, E)$. Since each component is connected, $\left|E_{i}\right| \geq\left|V_{i}\right|-1$. Then,

$$
|V|-c=\sum_{i=1}^{c}\left|V_{i}\right|-\sum_{i=1}^{c} 1=\sum_{i=1}^{c}\left(\left|V_{i}\right|-1\right) \leq \sum_{i=1}^{c}\left|E_{i}\right|=|E|
$$

In particular, for $(V, A)$, we have $n-c<n-1 \Longrightarrow c>1$. This means there exists an edge $e$ that connects two components of $(V, A)$.

Since $e$ is a bridge of $(V, A \cup\{e\})$, it does not add a cycle.

Claim 4.4.5. If the output of Algorithm 4.4.3 is $A=\left[e_{1}, \ldots, e_{r}\right]$, then $(V, A)$ is a spanning tree and $r=n-1$.

Proof. By construction, $(V, A)$ has no cycles (i.e., it is a tree). Suppose $(V, A)$ is not spanning. Then, it has at least two components and there exists an edge $e \notin A$ such that ( $V, A \cup\{e\}$ ) has no cycles because $G$ is connected. Now, either:

- $w(e)<w\left(e_{1}\right)$. This cannot happen because $e_{1}$ is the edge with the smallest weight.
- $w\left(e_{i}\right)<w(e)<w\left(e_{i+1}\right)$ for some $i$. This also does not work because if $e$ was considered after inserting $e_{i}$ and rejected, then that means that $e$ creates a cycle in $\left(V,\left\{e_{1}, \ldots, e_{i}\right\}\right)$. But by construction, $e$ does not create a cycle in $V(, A)$.
- $w(e)>w\left(e_{r}\right)$. This also does not make sense, because the algorithm would have included it in $A$ after selecting $e_{r}$.

Therefore, no such $e$ exists, which means that $(V, A)$ is spanning. Since $(V, A)$ is a spanning tree, we also get that $r=n-1$.

Claim 4.4.6. Let $(V, A)$ and $(V, T)$ be two spanning trees, and let $e$ be an edge in $T$ but not in $A$.

Then, there exists an edge $e^{\prime}$ in $A-T$ such that $\left(V, T+e^{\prime}-e\right)$ is still a spanning tree. Also, $e^{\prime}$ is on the cycle that $e$ creates in $A$.
(This is Theorem 5.2.4 from MATH 239)

Proof. Let $e=u v$. Then, $(V, A+e)$ contains a cycle $C=v w \cdots v$.
Since $T$ is a tree, $(V, T-e)$ has two connected components $T_{1}$ and $T_{2}$. Wlog, suppose $v \in T_{1}$. Then, $C$ starts in $V\left(T_{1}\right)$, immediately crosses to $V\left(T_{2}\right)$, and at some point later crosses back into $V\left(T_{1}\right)$. Therefore, there exists an edge $e^{\prime} \in E(C) \subseteq A+e$ connecting $T_{1}$ and $T_{2}$ that is in $A$ but not in $T$.

It follows that $\left(V, T+e^{\prime}-e\right)$ is a spanning tree by reconnecting those components.
Now, proceed by an exchange argument.

## Proposition 4.4.7

Let $A$ be the output of Algorithm 4.4.3 and $(V, T)$ be any spanning tree. Then, $(V, A)$ is a spanning tree with $w(A) \leq w(T)$.

Proof. We know that $(V, A)$ is a spanning tree from Claim 4.4.5.
Claim that $w(A) \leq w(T)$. We induct on the size of $T-A$. If $T-A=\varnothing$, then $A=T$ and naturally $w(A)=w(T)$.

Suppose $A \neq T$. Then, let $e \in T-A$. By Claim 4.4.6, there exists an edge $e^{\prime} \in A-T$ such that $\left(V, T+e^{\prime}-e\right)$ is a spanning tree and $e^{\prime}$ is on the cycle that $e$ creates in $A$.
Since we rejected $e$, it must have created a cycle in $A$. Therefore, it appeared in the sorted list after all elements in its induced cycle, in particular, $w\left(e^{\prime}\right) \leq w(e)$.

Then, if we let $T^{\prime}=T+e^{\prime}-e$, we have $w\left(T^{\prime}\right)=w(T)+w(e)-w\left(e^{\prime}\right) \leq w(T)$.
Also, since $T^{\prime}$ has one more edge in common with $A,\left|T^{\prime}-A\right|<|T-A|$. By the inductive hypothesis, $w(A) \leq w\left(T^{\prime}\right) \leq w(T)$.
Therefore, $A$ is optimal.

Now, consider how we can implement this optimally. Every vertex is initially in a component of just itself. Then, as edges are added, the components grow. To check if a cycle is formed, check if both ends of an edge are in the same component.

We need a data structure that allows us to quickly identify a set given an element belongs to (Find $(e))$ and also join two sets $\left(\operatorname{Union}\left(S_{1}, S_{2}\right)\right)$. With these operations, we can rewrite Kruskal's as:

```
Algorithm 4.4.8 GreedyMSTUnionFind \((G)\)
    \(T \leftarrow[]\)
    \(U \leftarrow\left\{\left\{v_{1}\right\}, \ldots,\left\{v_{n}\right\}\right\}\)
    sort edges by increasing weight
    for \(e \in E(G)\) sorted do
        if \(U . \operatorname{Find}\left(e_{k} \cdot 1\right) \neq U . \operatorname{Find}\left(e_{k} \cdot 2\right)\) then
            \(U . \operatorname{Union}\left(U . \operatorname{Find}\left(e_{k} \cdot 1\right), U . \operatorname{Find}\left(e_{k} \cdot 2\right)\right)\)
            \(T . \operatorname{Append}\left(e_{k}\right)\)
```

We can implement this with $U$ as an array of linked lists paired with an array of indices $X$ such that $e \in U[X[e]]$. Then, we can run Find in $O(1)$ time and Union in $O(n)$ time.

There will be $O(m)$ Find's and $O(n)$ Union's. The total time complexity is then $O\left(m \log m+n^{2}\right)$.
We can optimize this slightly. First, only traverse the smaller list when unioning. Also, have each linked list in $U$ keep track of its size and have an optional pointer to a continuation. Then, by setting the pointer, we can get concatenation in $O(1)$ even though the overall union is still $O(n)$ (because of the updates to $X$ ).

However, for any vertex $v$, the size of the list containing $v$ at least doubles every time we update $X[v]$. That means that $X[v]$ is updated $O(\log n)$ times, meaning the overall cost per union per vertex is $O(\log n)$ for $O(n \log n)$ total.

Therefore, we can do Kruskal's in $O(m \log m)$.

## Chapter 5

## Dynamic Programming

### 5.1 Introduction

Recall the Fibonacci numbers $F_{n}$ defined by $F_{0}=0, F_{1}=1, F_{n}=F_{n-1}+F_{n-2}$ with the naive algorithm

```
Algorithm 5.1.1 \(\operatorname{Fib}(n)\)
    if \(n=0\) then return 0
    else if \(n=1\) then return 1
    elsereturn \(\operatorname{FIB}(n-1)+\operatorname{FIB}(n-2)\)
```

Assuming we count additions as unit cost, the runtime is $T(n)=F_{n+1}+1 \in \Theta\left(\varphi^{n}\right)$ which is bad. Notice that we are recomputing small $F_{n}$ a bunch of times, but we actually only need each one once. We can instead cache:

```
Algorithm 5.1.2 FibCACHED \((n)\)
Require: \(T \leftarrow[0,1, \perp, \ldots, \perp]\) global array of size \(n\)
    if \(T[n]=\perp\) then
        \(T[n] \leftarrow \operatorname{FibCached}(n-1)+\operatorname{FibCAChed}(n-2)\)
    return \(T[n]\)
```

Also, notice that the dependency graph of which subproblems require each other is a DAG. Therefore, we can take an order on the dependencies and iterate: This is our dynamic programming

```
Algorithm 5.1.3 FibIterative( \(n\) )
    \(T \leftarrow[0,1, \perp, \ldots, \perp] 0\)-indexed array of size \(n\)
    for \(i=2, \ldots, n\) do
        \(T[i] \leftarrow T[i-1]+T[i-2]\)
    return \(T[n]\)
```

algorithm. In fact, we can optimize even more by noticing that we can discard all but the last two
elements of the array, giving a constant-space algorithm:

```
Algorithm 5.1.4 FibOptimal( \(n\) )
    \((u, v) \leftarrow(0,1)\)
    for \(i=2, \ldots, n\) do
        \((u, v) \leftarrow(v, u+v)\)
    return \(v\)
```

All these improved algorithms run in $O(n)$ time, a significant improvement.
We can give a general recipe for dynamic programming algorithms:

1. Identify the subproblem: We are retaining solutions in an array. What are the dimensions of the array? What does each entry represent? Where will the final answer be in the array?
2. Establish DP-recurrence: How does a subproblem contribute to a larger subproblem? What is the dependency between cells in the array?
3. Set base cases: Initialize the array with some non-recursively defined base cases.
4. Specify the order of computation: Clarify the DAG of subproblem dependencies. How does the algorithm maintain this order?
5. Recover the solution (if needed): What subproblem answers provide the problem solution? How, if necessary, do we traceback the solution from the subproblems?

We can often convert a DP algorithm into iterative loop(s). Distinguish divide and conquer algorithms which do not always solve subproblems and are not easily rewritten iteratively.

### 5.2 Interval Scheduling

Problem 5.2.1 (weighted interval scheduling)
Recall Problem 4.2.1. Now, add a weight $w_{i}$ to each interval. We choose a subset $T \subseteq[n]$ which maximizes $W=\sum_{i \in T} w_{i}$.

Example 5.2.2. Let $I=[[2,8],[2,4],[5,6],[7,9]]$ with weights $[6,2,1,2]$.

Solution. By inspection, since the weight $w_{1}=6>5=w_{2}+w_{3}+w_{4}$, the solution is $T=[1]$ with $W=6$.

Notice that we can split on whether we accept the last interval $I_{n}$ and write for example that the optimal weight

$$
W\left(I_{1}, \ldots, I_{n}\right)= \begin{cases}w_{n}+W\left(I_{m_{1}}, \ldots, I_{m_{s}}\right) & \text { if we choose } I_{n} \\ W\left(I_{1}, \ldots, I_{n-1}\right) & \text { if we do not }\end{cases}
$$

where $I_{m_{1}}, \ldots, I_{m_{s}}$ are the $s<n$ intervals not intersecting $I_{n}$.

Suppose we sort the intervals by finish time, i.e., $f_{i} \leq f_{i+1}$ for all $i$. Then, we have $m_{1}, \ldots, m_{s}=$ $1, \ldots, j$ where $j=\max \left\{i: f_{i}<s_{n}\right\}$ because $I_{n}$ is the last interval with the latest finish time, so we only need to compare its start time with earlier intervals' finish times. (If $j$ does not exist just return $w_{n}+0$.)

We need to calculate the $j$-values for every $i$ :

```
Algorithm 5.2.3 FindJs \(\left(A, s_{1}, \ldots, s_{n}, f_{1}, \ldots, f_{n}\right)\)
    \(j \leftarrow\) array of size \(n\)
    \(f_{0} \leftarrow \infty\)
    \(i \leftarrow 1\)
    for \(k=0, \ldots, n\) do
        while \(i \leq n\) and \(f_{k} \leq s_{A[i]}<f_{k+1}\) do
            \(j[i] \leftarrow k\)
            \(i++\)
    return \(j\)
```

where $A$ is a sorting permutation such that $\left(s_{A[i]}\right)$ is non-decreasing. This runs in $O(n \log n)+$ $O(n)=O(n \log n)$ time.

Now, for the main procedure, we define $W[i]$ as the maximal weight possible with the intervals $I_{1}, \ldots, I_{i}$.

Then, for $W[0]=0$ and $i \geq 1, W[i]=\max \left\{W[i-1], w_{i}+W[j[i]]\right\}$.
Since $W[i]$ depends only on entries in $W$ before it, we can just iterate on $i=1, \ldots, n$ in $O(n)$ time.

```
Algorithm 5.2.4 InTERVALSCHEDULING \(\left(s_{1}, \ldots, s_{n}, f_{1}, \ldots, f_{n}, w_{1}, \ldots, w_{n}\right)\)
Require: intervals are sorted by finish time
    \(A \leftarrow\) sorting permutation of \(s_{1}, \ldots, s_{n}\)
    \(j \leftarrow \operatorname{FindJs}\left(A, s_{1}, \ldots, s_{n}, f_{1}, \ldots, f_{n}\right)\)
    \(W \leftarrow 0\)-indexed array of size \(n\)
    \(W[0] \leftarrow 0\)
    for \(i=1, \ldots, n\) do
        \(W[i] \leftarrow \max \left\{W[i-1], w_{i}+W[j[i]]\right\}\)
    return \(W[n]\)
```

This gives a total time for the algorithm of $O(n \log n)+O(n)=O(n \log n)$.

### 5.3 Knapsack Problem

Problem 5.3.1 (0/1 knapsack)
Suppose we have items with weights $w_{1}, \ldots, w_{n}$ and values $v_{1}, \ldots, v_{n}$ but our knapsack has capacity $W$. We want to select items $S \subseteq\{1, \ldots, n\}$ satisfying $\sum_{i \in S} w_{i} \leq W$ and maximizes $\sum_{i \in S} v_{i}$.

Example 5.3.2. $\mathbf{w}=[3,4,6,5], \mathbf{v}=[2,3,1,5], W=8$.

Solution. The optimal $S=\{1,4\}$ with weight $3+5=8$ and value $2+5=7$.

For each item $n$, we can either choose it or we can not. Let $O[W, n]$ be best value for a knapsack of capacity $W$ and considering only the items $1, \ldots, n$. Then, $O[W, n]$ is either $v_{n}+O\left[W-w_{n}, n-1\right]$

Lecture 17
(07/06) or $O[W, n-1]$.

We can initialize $O[0, i]=0$ for all $i$ and $O[w, 0]=0$ for all $w$. To be able to calculate $O[W$, $n]$, we must have already calculated $O\left[W-w_{n} . . W, n-1\right]$. In particular, if we iterate on $n$ first, we can guarantee that the entire row $O[, n-1]$ exists before considering $O[W, n]$ :

```
Algorithm 5.3.3 01KNAPSACK \(\left(v_{1}, \ldots, v_{n}, w_{1}, \ldots, w_{n}, W\right)\)
    \(O \leftarrow 0\)-indexed array of size \((n+1) \times(W+1)\)
    \(O[0,] \leftarrow \mathbf{0} ; O[, 0] \leftarrow \mathbf{0}^{\top}\)
    for \(i=1, \ldots, n\) do
        for \(w=1, \ldots, W\) do
            if \(w_{i}>w\) then
                \(O[w, i] \leftarrow O[w, i-1]\)
            else
                \(O[w, i] \leftarrow \max \left\{v_{n}+O\left[W-w_{n}, n-1\right], O[W, n-1]\right\}\)
    return \(O[W, n]\)
```

The runtime here is obviously $\Theta(n W)$. We call this pseudo-polynomial because it is polynomial in $n$ (the size of the input) but also in $W$ (the value of an input). It is not polynomial because the size parameters are $n$ and $\lg W$, but we have $n 2^{\lg W}$.

### 5.4 Subsequence Problems

Problem 5.4.1 (longest increasing subsequence)
Find the longest (potentially discontinuous) increasing subsequence of an array $A[1 . . n]$ of integers.

Example 5.4.2. Given $A=[7,1,3,10,11,5,19]$, the longest increasing subsequence is $[1,3,10,11,19]$.

Notice that there are $\Theta\left(2^{n}\right)$ subsequences, so brute force is very bad here.
Suppose we try doing DP and storing $\ell[i]$ as the longest increasing subsequence of $A[1 . . i]$. This doesn't work, since we can't immediately deduce $\ell[i+1]$ from just $\ell[i]$ and $A$.

We could instead store into $L[i]$ a pair of the length and the last entry $(\ell, c)$. Then, we can add on the next element $L[i] \leftarrow(\ell+1, A[i])$, but what is $L[i]$ if we do not select $A[i]$ ?

Alternatively, let $L[i]$ be the length of the longest increasing subsequence of $A[1 . . i]$ that ends with $A[i]$. Then, $L[1]=1$. The longest increasing subsequence $S_{i}$ ending at $A[i]$ either looks like $[\ldots, A[j], A[i]]=\left[\ldots S_{j}, A[i]\right]$ for some $j$ or just $[A[i]]$.

```
Algorithm 5.4.3 LongestIncreasingSubsequence ( \(A[1 . . n]\) )
    \(L \leftarrow\) array of size \(n\)
    \(L[1] \leftarrow 1\)
    for \(i=2, \ldots, n\) do
        \(L[i] \leftarrow 1 \quad \triangleright S_{i}=[A[i]]\)
        for \(j=1, \ldots, i-1\) do \(\quad \triangleright S_{i}=\left[\ldots S_{j}, A[i]\right]\)
                if \(A[j]<A[i]\) then
                    \(L[i] \leftarrow \max \{L[i], L[j]+1\}\)
    return \(\max L\)
```

This algorithm runs in $\Theta\left(n^{2}\right)$ time which is much faster than $\Theta\left(2^{n}\right)$. Note that we don't return the actual sequence here, only its length, but it is trivial to find the sequence from the array $L$.

Problem 5.4.4 (longest common subsequence)
Given two arrays of characters (strings) $A[1 . . n]$ and $B[1 . . m]$, find the maximum length of a (potentially discontinuous) subsequence common to both $A$ and $B$.

Example 5.4.5. For $A=$ blurry and $B=$ burger, we should return burr for $k=4$.

As with Problem 5.3.1, we have to work in a 2D problem space. Let $M[i, j]$ be the longest subsequence length between $A[1 . . i]$ and $B[1 . . j]$. Zero out $M[0$,$] and M[, 0]$. Then, $M[i, j]$ will be the greatest of either (1) ignoring $B[j]$, (2) ignoring $A[i]$, or (3) adding $A[i]=B[j]$ :

```
Algorithm 5.4.6 LongestCommonSubsequence ( \(A[1 . . n], B[1 . . m])\)
    \(M \leftarrow 0\)-indexed array of size \(n+1 \times m+1\)
    \(M[0,] \leftarrow \mathbf{0} ; M[, 0] \leftarrow \mathbf{0}^{\top}\)
    for \(i=1, \ldots, n\) do
        for \(j=1, \ldots, m\) do
            \(M[i, j] \leftarrow \max \{M[i, j-1], M[i-1, j]\}\)
            if \(A[i]=B[j]\) then
                \(M[i, j] \leftarrow \max \{M[i, j], 1+M[i-1, j-1]\}\)
    return \(M[n, m]\)
```

Notice that because we iterate by $i$ first, $M[i-1,0 . . m]$ will have values. Also, since we are iterating by increasing $j, M[i, 1 . . j-1]$ will be calculated. Therefore, this algorithm works and runs in $\Theta(n m)$ time.

Problem 5.4.7 (edit distance)
Given two arrays of characters $A[1 . . n]$ and $B[1 . . m]$, what is the minimum number of add, delete, or change operations are required to turn $A$ into $B$ ?

Example 5.4.8. For $A=$ snowy, $B=$ sunny, the edit distance is 3 .
Both snowy $\rightarrow$ sunny and snowy $\rightarrow$ sunny each take 3 operations.

Let $D[i, j]$ be the edit distance between $A[1 . . i]$ and $B[1 . . j]$. Then, $D[0, j]=j$ for all $j$ (add $j$ characters to the empty string) and $D[i, 0]=i$ for all $i$ (add $i$ characters to the empty string). Otherwise, the value of $D[i, j]$ is the minimum of:

- Changing the last character: $D[i-1, j-1]+\delta_{A[i] B[j]}$
- Deleting $A[i]$ and matching $A[1 . . i-1]$ with $B[1 . . j]: D[i-1, j]+1$
- Adding $B[j]$ and matching $A[1 . . i]$ with $B[1 . . j-1]: D[i, j-1]+1$

Computing all values of $D$ takes $\Theta(m n)$ time.

### 5.5 Graph Algorithms

Problem 5.5.1 (optimal BST)
Given objects indexed by $1, \ldots, n$ with probabilities of access $p_{1}, \ldots, p_{n}\left(\right.$ with $\left.\sum p_{i}=1\right)$, what is the optimal binary search tree that minimizes the expected access time?

This problem is similar to the greedy Huffman tree problem (where frequencies are given instead of probabilities) and finding an optimal ordering for a linked list (greedily sort by probability).

The expected access time is $\sum_{i=1}^{n} p_{i}(\operatorname{depth}(i)+1)$.

Example 5.5.2. A possible BST with $n=6$ with the cost of each node:

We will split into subproblems based on where we place the root of a subtree. Let $M[i, j]$ be the minimal cost for a tree of the items $\{i, \ldots, j\}$ and $M[i, j]=0$ when $j<i$. If we select $k$ as the root of the $i, j$-subtree, then the cost of the tree is the cost of the $i, k-1$ and $k+1, j$ subtrees plus $p_{k}$.

When we place a subtree beneath $k$, the depth of every node increases by 1 . That is, we can take the weight from the $M$ array and add on one more copy of $p_{\ell}$ for each node $\ell$ in the subtree:

Then,

$$
\begin{aligned}
M[i, j] & =\min _{i \leq k \leq j}\left(M[i, k-1]+\sum_{\ell=i}^{k-1} p_{\ell}+p_{k}+M[k+1, j]+\sum_{\ell=k+1}^{j} p_{\ell}\right) \\
& =\min _{i \leq k \leq j}(M[i, k-1]+M[k+1, j])+\sum_{\ell=i}^{j} p_{\ell}
\end{aligned}
$$

Notice that $\sum_{\ell=i}^{j} p_{\ell}=\sum_{\ell=1}^{j} p_{\ell}-\sum_{\ell=1}^{i-1} p_{\ell}$. We can cache these sums in $O(n)$ time. We now have our algorithm:

```
Algorithm 5.5.3 \(\operatorname{OptimaLBST}\left(p_{1}, \ldots, p_{n}\right)\)
    \(S[0] \leftarrow 0\)
    for \(i=1, \ldots, n\) do
        \(S[i] \leftarrow S[i-1]+p_{i}\)
    for \(i=1, \ldots, n+1\) do
        \(M[i, i-1] \leftarrow 0\)
    for \(d=0, \ldots, n-1\) do \(\quad \triangleright d=j-i\)
        for \(i=1, \ldots, n-d\) do
                \(j \leftarrow d+i\)
                \(M[i, j] \leftarrow \min _{i \leq k \leq j}(M[i, k-1]+M[k+1, j]+S[j]-S[i-1])\)
```

which runs in $O\left(n^{3}\right)$ time.

Problem 5.5.4 (largest independent set of a tree)
Given a tree $T=(V, E)$, what is the largest independent set (i.e., a set $S \subseteq V$ such that $\left.S^{2} \cap E=\varnothing\right) ?$

Example 5.5.5. If $G=4$

Let $I[v]$ be the size of the largest independent set of the subtree rooted at $v$. We can either include $v$ in the independent set or exclude it. If we include it, take the sum of the $I[u]$ for each grandchild $u$. Otherwise, we take the sum of the $I[u]$ for the children of $u$.

We will have to calculate $I$ bottom-up, but otherwise this gives us an $O(n)$ algorithm.

### 5.6 Shortest Path Revisited: Bellman-Ford

Recall Problem 4.3.3 (single-source shortest path) that we solved with Dijkstra's.

Lecture 19 (07/18)

Let $\delta_{i}(s, v)$ be the length of the shortest path $s \rightsquigarrow v$ with at most $i$ edges and $\infty$ if no such path exists.

Then, we get a base case $\delta_{0}(s, s)=0$ and $\delta_{0}(s, v)=\infty$ for $v \neq s$. By construction, $\delta(s, v) \leq \delta_{i}(s, v)$ for all $i$ and $v$. In particular, if there are no negative cycles, $\delta_{n-1}(s, v)=\delta(s, v) .{ }^{1}$ Therefore, we only need to calculate for $i=0, \ldots, n-1$.

Now, consider $\delta_{i}(s, v)$. The size of the shortest path is either exactly $i$ or at most $i-1$. If it is at most $i-1$, then $\delta_{i}(s, v)=\delta_{i-1}(s, v)$. Otherwise, there is an $i^{\text {th }}$ edge $u v$ and the length is exactly $\delta_{i-1}(s, u)+w(u v)$. That is, we can calculate all of $\delta_{i-1}$ by:

```
Algorithm 5.6.1 BellmanFord \((G, s)\)
    \(d_{0} \leftarrow[\infty, \ldots, \infty] ; d_{0}[s] \leftarrow 0\)
    parent \(\leftarrow[\perp, \ldots, \perp]\); parent \([s] \leftarrow s\)
    for \(i=1, \ldots, n-1\) do
        for \(v \in V\) do
            \(d_{i}[v] \leftarrow d_{i-1}[v]\)
            for \(u\) neighbour of \(v\) do
                if \(d_{i-1}[u]+w(u, v)<d_{i}[v]\) then
                    \(d_{i}[v] \leftarrow d_{i-1}[u]+w(u v)\)
                    parent \([v]=u\)
```

The runtime here is not great $\left(O\left(n^{2} m\right)\right)$. We can improve by noticing that we can use only one $d$ array. Instead of iterating over edges incident to vertices, iterate over every edge $u v$. If $u$ and $v$ are both undiscovered, we get $d[u]+w(u v)<d[v]=\infty+w(u v)<\infty$ which is false, so the effect is the same:

```
Algorithm 5.6.2 BellmanFord2.0( \(G, s\) )
    \(d \leftarrow[\infty, \ldots, \infty] ; d[s] \leftarrow 0\)
    parent \(\leftarrow[\perp, \ldots, \perp]\); parent \([s] \leftarrow s\)
    for \(i=1, \ldots, n-1\) do
        for \(u v \in E\) do
            if \(d[u]+w(u, v)<d[v]\) then
                \(d[v] \leftarrow d[u]+w(u v)\)
                parent \([v]=u\)
```

but we only use $O(n m)$ time, which is better (compare with Dijkstra's $O((n+m) \log m)$ ).
We now prove that this simplification (and the original) works. Call the operation of considering a new edge and setting $d[v] \leftarrow \min \{d[v], d[u]+w(u, v)\}$ a relaxation.

Lecture 20
(07/18)

Claim 5.6.3. After iteration $i$, we have $d \leq d_{i}$. Also, $d[v]$ only decreases through relaxations.

Proof. Induct on $i$. At $i=0, d_{0}=[0, \infty, \ldots, \infty] \leq d$.

[^1]Suppose $d \leq d_{i-1}$. Since we are assigning $d[v] \leftarrow \min \{d[v], \ldots\}$, obviously $d[v]$ can only decrease with each relaxation. Then, $d \leq d_{i-1}$ holds throughout the iteration. For each vertex:

so at the end of the iteration, $d \leq d_{i}$.

Claim 5.6.4. When there are no negative cycles: if $\delta(s, u) \leq d[u]$ and $d(s, v) \leq d[v]$ before a relaxation, then $\delta(s, v) \leq d[v]$ afterwards.

Proof. The triangle inequality $\delta(s, v) \leq \delta(s, u)+w(u, v)$ holds for all $u v \in E$ if there is no negative cycle. Then, if $\delta(s, u) \leq d[u]$, we get $\delta(s, v) \leq d[u]+w(u, v)$. We are also given $\delta(s, v) \leq d[v]$. Therefore, $\delta(s, v) \leq \min \{d[v], d[u]+w(u, v)\}$, so $\delta(s, v) \leq d[v]$ afterwards.

## Proposition 5.6.5

If there are no negative cycles, for all $i$, after iteration $i, \delta(s, v) \leq d[v] \leq \delta_{i}(s, v)$ for all $v$. After $n-1$ iterations, $\delta(s, v)=d[v]$.

Proof. We get $\delta(s, v) \leq d[v]$ from Claim 5.6.4 and $d[v] \leq \delta_{i}(s, v)$ from Claim 5.6.3.
Recall that $\delta(s, v)=\delta_{n-1}(s, v)$ if there are no negative cycles. Then, at iteration $i=n-1$, we have $\delta(s, v) \leq d[v] \leq \delta_{n-1}(s, v)=\delta(s, v)$, i.e., $\delta(s, v)=d[v]$.

## Proposition 5.6.6

If there is a negative cycle, then there must be an edge $u v$ with $d[u]>d[v]+w(u, v)$ (i.e., violates the triangle inequality).

Proof. Let $C=v_{1}, \ldots, v_{k}=v_{1}$ be a negative cycle with $\sum w\left(v_{i}, v_{i+1}\right)<0$. Suppose for a contradiction that all $d\left[v_{i+1}\right] \leq d\left[v_{i}\right]+w\left(v_{i}, v_{i+1}\right)$. Sum the inequality around the cycle:

$$
\begin{aligned}
\sum_{i=1}^{k-1} d\left[v_{i+1}\right] & \leq \sum_{i=1}^{k-1}\left(d\left[v_{i}\right]+w\left(v_{i}, v_{i+1}\right)\right) \\
\sum_{i=1}^{k-1} d\left[v_{i+1}\right] & \leq \sum_{i=1}^{k-1} d\left[v_{i}\right]+\sum_{i=1}^{k-1} w\left(v_{i}, v_{i+1}\right) \\
0 & \leq \sum_{i=1}^{k-1} w\left(v_{i}, v_{i+1}\right)
\end{aligned}
$$

which means this is a positive cycle. Contradiction.
Therefore, we can test for a negative cycle after calculating $d$ by analyzing all edges and finding one where the triangle inequality does not hold.

### 5.7 All Shortest Paths: Floyd-Warshall

We now solve a variation of the single-source shortest-path problem.

Problem 5.7.1 (all shortest paths)
Given a graph $G=(V, E)$ with weights $w: E \mapsto \mathbb{R}$, find every value of $\delta(u, v)$ for all $u, v \in V$.

Floyd-Warshall is very simple, but slower than other algorithms. Notice that we are not restricting weights to be non-negative, but still disallow negative cycles.

Instead of setting the path length as the subproblem parameter like Bellman-Ford, we instead restrict which vertices can be used.

Let $D_{i}\left(v_{j}, v_{k}\right)$ be the length of the shortest path $v_{j} \rightsquigarrow v_{k}$ with all intermediate vertices in $\left\{v_{1}, \ldots, v_{k}\right\}$.
Initially, $D_{0}\left(v_{j}, v_{k}\right)= \begin{cases}0 & j=k \\ w\left(v_{j}, v_{k}\right) & v_{j} v_{k} \in E \\ \infty & \text { otherwise }\end{cases}$
Then, by construction, $D_{n}\left(v_{j}, v_{k}\right)=\delta\left(v_{j}, v_{k}\right)$
Claim 5.7.2. $D_{i}\left(v_{j}, v_{k}\right)=\min \left\{D_{i-1}\left(v_{j}, v_{k}\right), D_{i-1}\left(v_{j}, v_{i}\right)+D_{i-1}\left(v_{i}, v_{k}\right)\right\}$

Proof. The shortest path $P: v_{j} \rightsquigarrow v_{k}$ either goes through $v_{i}$ or does not. Since there are no negative cycles, it can only go through it exactly once.

This gives the algorithm:

```
Algorithm 5.7.3 FloydWarshall \((G)\)
    initialize \(D_{0}\) as above
    for \(i=1, \ldots, n\) do
        for \(j=1, \ldots, n\) do
            for \(k=1, \ldots, n\) do
                \(D_{i}\left[v_{j}, v_{k}\right] \leftarrow \min \left\{D_{i-1}\left[v_{j}, v_{k}\right], D_{i-1}\left[v_{j}, v_{i}\right]+D_{i-1}\left[v_{i}, v_{k}\right]\right\}\)
```

which has runtime $O\left(n^{3}\right)$ (similar to running Bellman-Ford on every source in $O\left(m n^{2}\right)$ ).

## Chapter 6

## Complexity Theory

### 6.1 Introduction

We consider in general decision problems.

Lecture 21
(07/20)

Definition 6.1.1 (decision problem)
A map that takes a problem instance and returns a truth value. In general, a map $\mathrm{A}: \mathcal{J}(\mathrm{A}) \rightarrow$ $\{0,1\}$. We call an instance where $\mathrm{A}(I)=1$ a yes-instance (otherwise a no-instance).

Note that we can consider a problem instance $I \in \mathcal{J}(\mathrm{~A})$ as a natural number (formally) since we typically represent them as some sort of binary string.

## Proposition 6.1.2

Almost all decision problems are undecidable.

Proof. Notice that we can represent the map $\mathrm{A}: \mathbb{N} \rightarrow\{0,1\}$ as a binary string $\mathrm{A}(0) \mathrm{A}(1) \cdots$. Then, assuming there is no structure here, we can perform a diagonal argument to show that the problem is uncountably infinite.

However, solutions are a finite bit string, which are only countably infinite.

## Definition 6.1.3 ( P )

The class of decision problems that can be solved in polynomial time, i.e., in $O\left(n^{p}\right)$ time for $p>0$.

Definition 6.1.4 (polynomial reduction)
A problem A is reducible to a problem B if there exists a function $f: \mathcal{J}(\mathrm{A}) \rightarrow \mathcal{J}(\mathrm{B})$ such that yes-instances are mapped to yes-instances (no-instances to no-instances) and $f$ is computable in $O\left(n^{p}\right)$ for some $p$. We write $\mathrm{A} \leq_{\mathrm{p}} \mathrm{B}$.

As with normal orders, we say that $A={ }_{p} B \Leftrightarrow A \leq_{p} B \wedge B \leq_{p} A$.
Suppose that $\mathrm{A} \leq_{\mathrm{P}} \mathrm{B}$ and $\mathrm{B} \in \mathrm{P}$. Then, given an instance $I \in \mathcal{J}(\mathrm{~A})$, we can solve it by solving $f(I)$ (which is computed in polynomial time) as an instance of $B$ (which is polynomial).

Lemma 6.1.5 (transitivity of polynomial reduction)
If $A \leq_{p} B$ and $B \leq_{p} C$, then $A \leq_{p} C$.

Proof. By definition, there exists $f: \mathcal{J}(\mathrm{A}) \rightarrow \mathcal{J}(\mathrm{B})$ and $g: \mathcal{J}(\mathrm{B}) \rightarrow \mathcal{J}(\mathrm{C})$. Then, $g \circ f: \mathcal{J}(\mathrm{A}) \rightarrow \mathcal{J}(\mathrm{C})$ and preserves yes-no.

Lemma 6.1.6 (proving hardness)
Suppose $A \leq_{P} B$ and we know that $A \notin P$. Then, $B \notin P$.

Proof. By contradiction. If $\mathrm{B} \in \mathrm{P}$, then we could solve A in polynomial time.

### 6.2 Sample Reductions

Recall from graph theory that a clique is a set of vertices $S \subseteq V(G)$ such that for all $u, v \in S$, $u v \in E(G)$. Similarly, an independent set is a set $S$ of vertices such that for all $u, v \in S, u v \notin E(G)$.

## Proposition 6.2.1

Consider the problems Clique (does a graph $G$ have a clique of size at least $k$ ?) and IS (does a graph $G$ have an independent set of size at least $k$ ?). Then, Clique $=_{\mathrm{p}}$ IS.

Proof. Notice that a clique is the "inverse" of an independent set (i.e., a clique is a set $S \subseteq V$ such that $S^{2} \subseteq E$ while an independent set is a set $S \subseteq V$ such that $S^{2} \sqcup E$ ).

Define the inverse graph $\bar{G}=(V, \bar{E})$ where $\bar{E}=V^{2}-E$. Then, given an instance of one problem $(G, k)$, we can make a call to the other problem $(\bar{G}, k)$. The inversion takes $O(m)$ time, which is polynomial.

Therefore, Clique $=\mathrm{p}$ IS.
Recall again that a vertex cover is a set $S \subseteq V$ such that $\{u v\} \cap S \neq \varnothing$ for all $u v \in E$ (i.e., at least one endpoint of every edge is in $S$ ).

## Proposition 6.2.2

IS $={ }_{\mathrm{p}} \mathrm{VC}$ (does $G$ contain a vertex cover of at most $k$ vertices?)

Proof. Notice that $S$ is a vertex cover if and only if $V \backslash S$ is an independent set.
Suppose $S$ is a vertex cover but $V \backslash S$ is not independent. That is, there exists $x, y \in V \backslash S$ such that $x y \in E$. But at least one of $x$ or $y$ must be in $S$ since it is a vertex cover. Contradiction.

Conversely, suppose $V \backslash S$ is independent but $S$ is not a vertex cover. Then, there is an edge $x y \in E$ with $x, y \notin S$. But that means $x$ and $y$ are adjacent in the independent set $V \backslash S$. Contradiction.

Therefore, $G$ has a vertex cover of size at most $k$ if and only if $G$ has an independent set of size at least $n-k$. We map VC instances $(G, k) \leftrightarrow(G, n-k)$ instances of IS. This map obviously takes polynomial time, so $\mathrm{IS}={ }_{\mathrm{p}} \mathrm{VC}$.

Therefore, finding cliques, independent sets, and vertex covers are all equivalent up to polynomialtime reducibility.

## Proposition 6.2.3

Consider the problems HC (does a graph $G$ have a Hamiltonian cycle?) and HP (does a graph $G$ contain a Hamiltonian path?). Then, $\mathrm{HC}={ }_{\mathrm{p}} \mathrm{HP}$.

Proof. Consider first the Hamiltonian $s, t$-path problem (does $G$ contain a Hamiltonian path $s \rightsquigarrow$ $t$ ?) and that we are given an instance ( $G, s, t$ ). Then, $(G, s, t)$ is a yes-instance if and only if $G+x+s x+t x$ is a yes-instance of HC.

Likewise, a Hamiltonian cycle $s \rightsquigarrow t s$ exists if and only if ( $G-s t$ ) is a yes-instance of the Hamiltonian $s, t$-path problem.

Since both of those operations are polynomial time removals/additions of vertices/edges, we have that the Hamiltonian $s, t$-path problem $={ }_{\mathrm{p}} \mathrm{HC}$.

Now, consider the actual problem HP. We can show HP $\leq_{p} H C$ in the same way. Consider a graph $G$ and add a vertex $x$ adjacent to all vertices. Then, this new graph $G^{\prime}$ has a Hamiltonian cycle if and only if $G$ has a Hamiltonian path.

Finally, to show $\mathrm{HC} \leq_{\mathrm{P}} \mathrm{HP}$, consider a graph $G$ with a Hamiltonian cycle $s \rightsquigarrow t \rightsquigarrow s$. Create $G^{\prime}$ by splitting an arbitrary vertex $t$ into two vertices $t$ and $t^{\prime}$ such that $s \rightsquigarrow t$ and $t^{\prime} \rightsquigarrow s$. Then, because of the way we divided the edges of $t$, a Hamiltonian path in $G^{\prime}$ must start at $t$ and end at $t^{\prime}$. It follows that $G$ has a Hamiltonian cycle if and only if $G^{\prime}$ has a Hamiltonian path.

Therefore, $\mathrm{HC}=\mathrm{HP}$.
Recall from CS 245 that a binary function of $n$ variables is satisfiable if there exists an assignment of truth values to variables that makes the expression true. Recall also that we may write any binary function in conjunctive normal form, i.e., as a conjunction of a finite set of $m$ disjunctions of literals (either variables or their negations).

Proposition 6.2.4
Consider the problem 3SAT (is a CNF formula of at most 3 literals per clause satisfiable?). Then, 3 SAT $\leq_{P}$ IS.

Proof. The reduction will take advantage of the fact that to make the whole formula true, we must select at least one literal from each disjunction to make true.

Construct a graph of all the literals. Attach each literal in the same clause. Attach any two complementary literals.

Then, ask if there is an independent set of size at least $m$.
For correctness, suppose that $G$ has an independent set $S$ of size at least $m$. Assign each variable $x=\top$ if $\exists x \in S$ and $x=\perp$ if $\exists \bar{x} \in S$. Since literals are adjacent to their complements, $x$ will either be set to true or false (or neither, in which case we just assign $\top$ arbitrarily). Also, since literals are adjacent in $G$ if they are from the same clause, the $m$ elements of the independent set must come from each of the $m$ clauses by the pigeonhole principle. Therefore, this assignment satisfies $G$.

Conversely, suppose there exists a satisfying assignment. Then, simply construct the according independent set. Because edges exist only between contradictory literals or between clauses, the set will indeed be independent.

Therefore, 3 SAT $\leq_{P}$ IS.

### 6.3 NP-completeness

Consider the SubsetSum problem, where we are given a set of integers $S$ and must find a subset $T \subseteq S$ such that $\sum_{x \in T} x=0$. This problem is hard.
However, suppose an oracle gives us $T$ and claims it has sum 0 . We can write a helper function $\operatorname{VERIfy}(I, C)$ which returns yes if $I$ is a yes-instance and $C$ is a valid certificate that proves $I$ is a yes-instance. In our example, VerifySubsetSum $(S, T)$ checks that indeed every element in $T$ is also in $S$ and also that they sum to 0 .

## Definition 6.3.1 (NP)

The class of decision problems with yes-instances that can be verified in polynomial time. Equivalently, the class of decision problems that can be solved by a non-deterministic algorithm in polynomial time.

For example, 3SAT is in NP because evaluating the clauses given a valid variable truth-value assignment can be done in polynomial time.

Lecture 23 (07/27)

Not all decision problems are in NP: for example, consider whether a graph is non-Hamiltonian. The no-instances are easily verifiable, but the yes-instances are hard.

Definition 6.3.2 (co-NP)
The class of decision problems with no-instances that can be verified in polynomial time.

Clearly, all problems in P are also in NP and co-NP: simply solve the problem in polynomial time. Therefore, $\mathrm{P} \subseteq N P$ and $P \subseteq$ co-NP. This leads to the most famous problem in computer science.

## Conjecture 6.3.3 <br> $P \stackrel{?}{=} N P$

To make deciding whether NP $\subseteq$ P easier, we create a notion of the "hardest" problems in NP.
Definition 6.3.4 (NP-complete)
A problem $X \in N P$ is NP-complete if for all $Y \in N P$, we have $Y \leq_{P} X$. Then, we write $X \in$ NPC.

Then, it immediately follows that $P=N P \Longleftrightarrow \exists X \in N P C, X \in P$.
Theorem 6.3.5 (Cook-Levin)
3SAT $\in$ NPC

This is a useful theorem, since once we have on NP-complete problem, we can just show that any other problem, for example IS, is NP-complete because 3 SAT $\leq_{p}$ IS.
Proof (sketch). Consider the CircuitSAT problem. We are given a DAG with labelled vertices. Inputs are marked with $x_{1}, \ldots, x_{n}$. Internal vertices are marked by Boolean operators and, or, and not. For example,

For a vertex $v$, is there some truth-value assignment to the $x_{i}$ 's that makes $v$ true?
We will show that CircuitSAT is NP-complete, and then that CircuitSAT $\leq_{p}$ 3SAT.
Let A $\in$ NP and $S$ be a yes-instance of A. We want to find an algorithm that checks of a certificate $t$ can prove that $S$ is indeed a yes-instance.

This verification algorithm is a Boolean function (i.e., it takes in $t$ as input and outputs a Boolean value), so we can write it as a circuit (recall from CS 245 that $\wedge, ~ \vee$, and $\neg$ are sufficient to write
any Boolean function). Therefore, we can just call CircuitSAT to find $t$, which is as good as solving $S$.

Therefore, $A \leq_{P}$ CircuitSAT, and CircuitSAT $\in$ NPC.
Now, notice that we can transform the CircuitSAT DAG into a set of conjunctive clauses with at most three literals:

Therefore, CircuitSAT $\leq_{p} 3 S A T$, which means that $3 S A T \in N P C$.
For reference, a list of NP-complete problems:

- 3SAT, SAT
- independent set, vertex cover, clique
- (directed) Hamiltonian cycle, Hamiltonian path
- travelling salesman
- subset sum
- 0/1 knapsack

We will show NP-completeness for Hamiltonian cycles and paths.

Theorem 6.3.6
3SAT $\leq_{p}$ DirectedHamiltonianCycle $\leq_{p}$ HamiltonianCycle

Proof. We begin by showing 3 SAT $\leq_{P}$ DirectedHamiltonianCycle. That is, given a formula, we must create a directed graph such that the formula is satisfiable if and only if the graph is Hamiltonian.

To do this, we will first create a graph with $2^{n}$ Hamiltonian cycles corresponding to each possible truth value assignment. Then, we will add vertices to constrain the valid cycles to those consistent with the given clauses.

TODO
To convert a directed graph $G$ to an undirected graph $G^{\prime}$, replace each vertex $v$ by $v_{i}, v_{m}$, and $v_{o}$ :

Suppose there is a directed Hamiltonian cycle in $G$. Then, we just have to follow it in $G^{\prime}$ to hit every vertex. If there is a Hamiltonian cycle in $G^{\prime}$, it must go

so we can construct the directed Hamiltonian cycle in $G$.
This takes polynomial time, so we have DirectedHamiltonianCycle $\leq_{p}$ HamiltonianCycle.
Then, by combining with Theorem 6.3.5 and Proposition 6.2.3, we have proved NP-completeness for HamiltonianCycle and HamiltonianPath.

## Chapter 7

## Final Review

Exercise 7.0.1. Suppose we want to schedule people be on call between time $S$ and $T$. If each of the $n$ people are available from $s_{i}$ to $t_{i}$, give a greedy algorithm to assign the minimum number of people.

Assume that the input is already sorted by start time $S \leq s_{1} \leq \cdots \leq s_{n} \leq T$.

Solution. Since we know we must start at $S$, consider all the intervals that start at $S$. Then, pick the one with the latest end time.

For each subsequent selection, consider all the intervals with start times before the last chosen end time and then select the one with the latest end time.

```
Algorithm 7.0.2 GreedyScheduleAssign \(\left(S, T,\left[s_{1}, t_{1}\right], \ldots,\left[s_{n}, t_{n}\right]\right)\)
    \(O \leftarrow \varnothing\)
    \(s \leftarrow S, o \leftarrow 1\)
    for \(i=1, \ldots, n\) do
        if \(s_{i} \leq s\) then
            if \(t_{i} \geq t_{o}\) then
            \(o \leftarrow i\)
        else
            \(O \leftarrow O \cup\{o\}\)
            \(s \leftarrow t_{o}\)
            \(o \leftarrow i\)
```

This runs in $O(n)$ time.

Exercise 7.0.3. An $i \times j$ rectangle is worth $P[i, j]$. Given an $n \times m$ rectangle, give a dynamic programming algorithm to find the optimal way to cut the rectangle into smaller rectangles.

Solution. Let $M[i, j]$ be the optimal value of a rectangle after considering subdivisions. Then, $M[i, j]$ is either:

- $P[i, j]$, the value without cutting;
- $M_{V}(i, j)=\max \bigcup_{1 \leq k \leq i}\{M[k, j], M[i-k, j]\}$, the maximum value of a vertical cut; or
- $M_{H}(i, j)=\underset{1 \leq k \leq j}{\max } \bigcup_{1 \leq}\{M[i, k], M[i, j-k]\}$, the maximum value of a horizontal cut.

Finally, we just iterate. Each of the $O(n m)$ iterations takes $O(n+m)$ time, so we have $O\left(n^{2} m+\right.$ $n m^{2}$ ).

Exercise 7.0.4. Consider the problem ModifiedSTPath: given an edge-weighted directed graph, is there a simple $s, t$-path (i.e., with no repeated vertices) with total weight at most $k$. What complexity class is ModifiedSTPath in?

Solution. We can find shortest paths in polynomial time, so find a shortest path via Dijkstra and check if its weight is at most $k$. This means ModifiedSTPath $\in \mathrm{P}$. Therefore, it is also in NP and co-NP.

Exercise 7.0.5. Show that ModifiedSTPath is NP-complete.

Proof. We will show that DirectedHamiltonianPath $\leq_{P}$ ModifiedSTPath.
Suppose we have a directed graph $G=(V, E)$ as input to DirectedHamiltonianPath. Notice that a Hamiltonian path is just a simple path with $|V|-1$ edges.

If we give every edge in $G$ a weight of -1 , then we can just count the edges that a path traverses. Let $G^{\prime}=(V \cup\{s, t\}, E \cup\{s v, t v: v \in V\})$ and $w(e)=-1$. Then, we can call ModifiedST$\operatorname{Path}\left(G^{\prime}, w, s, t,-(|V|+1)\right)$ which will respond "yes" exactly when there is a path of maximum length $|V|+1$ and "no" otherwise.

Therefore, DirectedHamiltonianPath $\leq_{p}$ ModifiedSTPath, which means ModifiedSTPath is NP-complete, as desired.

## List of Problems

1.2.1 Problem (contiguous subarrays) ..... 5
2.1.1 Problem (counting inversions) ..... 8
2.1.4 Problem (polynomial multiplication) ..... 9
2.1.6 Problem (matrix multiplication) ..... 10
2.1.7 Problem (closest pairs) ..... 10
2.1.8 Problem (selection) ..... 11
